CHAPTER ONE: INTRODUCTION

1. Purpose of the Study

Trade barriers have many different effects, which include price and quantity effects on trade and production, as well as employment, and welfare effects. These occur not only in the country applying them but also in other countries directly and indirectly affected by them. Our primary focus in this study is on ascertaining the impact of trade barriers on trade flows. More specifically, our purpose is to carry out a comprehensive investigation on the impact of a global trade liberalization on trade flows of each country/region involved in a multi-sectoral and multi-regional framework.

The direction of trade barriers' impact on trade flows is not an issue of major theoretical concern. The magnitude, however, is far from conclusive. On the direction, most international trade models offer unambiguous explanations. The standard partial equilibrium trade diagram as given in Figure 1.1, which is one of the most straightforward and widely used analytical tools, provides a clear illustration of the issue. Domestic demand and supply are given by D_d and S_d , respectively. World supply (S_w) is assumed to be completely elastic (otherwise it would slope up to the right), and the initial domestic price is P_0 . Domestic producers supply q_0 and imports are $Q_0 - q_0$.

Figure 1.1

If an *ad valorem* tariff t is imposed, the main effect is that domestic consumption and imports both decline, reflecting a higher price. Domestic

producers can produce more and capture a larger share of the domestic market. On the diagram, the import supply curve and prices facing domestic consumers increase to S_w' and P_1 (equal to $P_0(1+t)$), respectively. Domestic consumption and imports decline to Q_1 and $Q_1 - q_1$, respectively.

Given a picture as clear as Figure 1.1, how do we quantify the impact of trade barriers on trade flows? When we enter into the complexity of the real world, this question becomes much more difficult to answer than it appears to be. Our study is among the attempts at giving answer to this seemingly easy question. There are around 200 countries in the world, trading among one another thousands of commodities and services. One country's trade policy affects its own imports and exports which are the corresponding imports and exports of its trading partner countries. The interdependency among countries demands that a comprehensive study be multi-regional and multi-sectoral. The large number of regions and sectors makes the task most challenging.

Our study is an exercise through which we want to estimate the impact of a global trade liberalization on global trade flows. The trade liberalization of our study refers specifically to a scenario – the “Final Round” -- under which all countries involved remove their trade barriers completely. Our data on both trade barriers and trade flows are quite comprehensive in terms of sectoral details, which makes it possible for our estimation to be done at a very disaggregated level of economic sector classification. Moreover, since the trade liberalization is global, and countries involved are interdependent among one another, our approach of investigation is designed to explicitly model the interdependency and ensure the estimation consistency among the countries involved.

2. The structure of the study

Our study is an empirical analysis, and our approach is empirical modeling that tries to combine real world data with theory as part of the mix of inductive and deductive reasoning that make up economic analysis. We economists acknowledge our inability to conduct controlled experiments and therefore rely on economic models to estimate and simulate policy changes. Four elements determine the results of a policy simulation: the data that describe the situation under investigation, the form of equations, the value of estimated parameters and the scenarios. As a comprehensive investigation of the impact of trade barriers on trade flows, our study is structured to tackle each of the four major issues involved.

2.1 Data

The scope of our study is multi-regional and multi-sectoral, which entails a quite demanding data support. The trade data in our study is from the World Trade Database (WTDB), which provides very detailed information on bilateral commodity trade flows for over 150 countries. The trade protection data is from Trade Analysis and Information System (TRAINS), which provides information on tariffs, NTBs and trade flows for most OECD countries and some 80 developing countries. Both trade flow and trade protection data have to be aggregated for the purpose of doing empirical analysis by economic modeling.

However, to aggregate trade protection data, we need to take trade-flow weighted average of tariff rates and NTB indicators, so we must combine trade flow data from WTDB and trade protection data from TRAINS. This combination process was complicated by the fact that the two data sources are reported in two different classification systems. Trade flow data are reported in 4-digit Standard International Trade Classification (SITC) and trade protection data in 6-digit Harmonized Commodity Coding and Classification System (HS). Combining data on bilateral trade flows with that on trade protections, we construct a bilateral trade protection database, which describes in great detail the situation on global trade protection including both tariffs and NTBs and serves as the data foundation of our empirical analysis. One of the important features of the bilateral trade protection database is that it reveals the effective bilateral discrimination in a country's trade protection regime.

2.2 Parameter Estimation

The key parameters used in our study are those related to the sensitivities of how imports respond to changes in trade barriers including tariffs and NTBs. In the literature, parameters are normally determined in one of two ways: by assumptions or by estimation. Assumptions are based on relevant theoretical models, which may not necessarily be supported by empirical evidences. Since theoretical models abstract from reality, their implications for empirical analysis are limited. As far as estimation of key parameters is concerned, people can choose to either borrow the results from previous studies or carry out their own estimation. However, given the fact that a limited number of relevant empirical studies have been made so far and the lack of consensus in the literature on this issue, how much confidence should be put in the borrowed results is really a matter of judgement. Making one's own estimation of the parameters is time-consuming and may not necessarily lead to convincing improvement without strong support from quality data.

We, nevertheless, choose to carry out our own estimation using the data from the database that we constructed by combining WTDB and TRAINS. We use a model that is based on the monopolistic competition trade model and 1994 cross-country data on trade barriers, trade flows, and production to estimate the import-reducing effect of trade barriers including both tariffs and NTBs. Our sample covers a broad range of countries -- more than 70 in total -- including countries from the most developed ones like those in the G-7 group to the least developed ones such as Bangladesh. By pooling across both industries and countries, we can conduct the estimation based on a very large sample of data, an important advance over previous studies. Moreover, since we have access to the most updated and systematic data, the results from this study contribute to a better understanding of the recent situation on the relevant issues. Other studies, known to us, use now at least ten years old data. We estimate the effects of both tariffs and NTBs, with the latter being categorized into several different types according to their functional features. In the equation estimation, we specify an empirical model which is capable of capturing the stylized facts fairly well and helps generate more sensible and econometrically efficient estimates. Finally,

our econometric framework is designed to control for the simultaneous determination of trade flows, trade barriers and production.

2.3 Modeling approach

Our primary purpose is to model the impact of a global trade liberalization or a “Final Round”, a situation in which each country involved removes their respective trade barriers. A country’s imports will increase in response to the removal of trade barriers, and the magnitude of increase can be estimated based on the existing level of trade barriers and estimated sensitivities of imports with respect to the corresponding trade barriers. With each country involved increasing its imports as a consequence of trade liberalization, its exports will increase accordingly. The impact on a country’s exports can therefore be estimated by summing up all the impacts on its trading partners’ imports. This is the basic approach that we adopt to estimate the impact on trade flows of a global trade liberalization. Our estimation is made with close attention to the sectoral details of trade flows.

However, an issue arises which is related to the effective bilateral discrimination of a country’s trade protection regime. Given that an importing country may treat its trading partners differently, after the trade barriers are removed, its imports from countries which faced high barriers should increase more than from those countries which were previously treated favorably. In another word, although the country involved may increase its overall level of imports following the trade liberalization, it does not necessarily increase its imports from each of its trading partners by proportionally the same amount. From the perspective of an exporting country, its exports to a specific country could increase or decrease depending on how it is treated by its trading partners in terms of trade barriers prior to the trade liberalization. Therefore, a complete estimation should somehow model this ‘sourcing’ effect of trade liberalization.

We conduct two studies in two different approaches. In the first one, we estimate the impact on US imports and exports under a scenario where the US as well as its trading partners remove their respective trade barriers, including tariffs and NTBs. In this study, our purpose is to highlight the impact of the difference in the degree of trade protection imposed by the US as well as its trading partners. Here we do not address the issue of bilateral discrimination; instead we assume that US trading partners increase their imports from the US in proportion to their overall level of import increase as a result of the global trade liberalization.

In the second study, we expand the scope and simulate the impact of global trade liberalization on 16 counties and regions, which, together, cover the global trade flows. This extensive study is made possible by employing a Bilateral Trade Model (BTM). The function of BTM is to allocate each country’s imports to their countries of origin in accordance with the commodity-share matrices. The sum of all the allocations of a particular product to one country then yields a consistent estimate of exports of that country. The BTM helps simulate the impact of trade liberalization on the 16 countries and regions all at once, which could otherwise entails very onerous computational work.

Moreover, with BTM's help, we are also able to model explicitly the bilateral discrimination and identify its impact on a country's trade flows amidst a global trade liberalization.

Both studies are done with close attention to sectoral details. The first study covers fifty-one trading sectors in the US economy, and the second one covers 120 sectors. We are able to identify how trade flows of each sector in a country's economy will be impacted by the global trade liberalization. The aggregate impact is estimated by summing up across sectors. This bottom-up approach ensures the estimation to be consistent among countries at sectoral as well as aggregate level.

3. Plan of Report

The report is presented in the next six chapters. Chapter 2 considers data preparation. The issue of trade protection measurement is first discussed, followed by a description of the two original data sources – TRAINS and WTDB. Then, we describe our approach of combining the two database to create a bilateral trade protection database which serves as the data foundation of our further studies. After presenting some pieces of information from the bilateral trade protection database, we make a preliminary statistical analysis of the data in order to give an overall picture of the situation on global trade protection before digging into details of modeling.

In Chapter 3, we estimate the import-reducing effect of trade barriers and derive the estimates of key parameters, i.e. the sensitivities of imports with respect to tariffs and NTBs. A literature review is conducted first, which helps identify the pros and cons of various ways of conducting the estimation and to determine an empirical model based on the monopolistic competition trade model. The technical details of econometric estimation are then discussed, and data requirements other than trade flows and trade protection indicators are described. Finally, we present and discuss the estimation results and their implications for determining the estimates of the sensitivities of import with respect to tariffs and NTBs.

Chapter 4 focuses on one particular country and tries to answer the question: what would happen to U.S. imports and exports if all countries removed their respective existing tariffs and NTBs on all commodities? The econometric study in Chapter 3 provides estimates on the relationship between imports and the trade barriers including tariffs and some forms of NTBs. As an application of the previous study, two related aspects are covered: the facts -- presentation of the data from our database on the tariff and non-tariff barriers faced by U.S. imports and exports; and the counter-factual analysis -- estimation of changes in U.S. imports and exports assuming all countries remove their existing tariffs and NTBs on all commodities.

In Chapter 5, we expand the scope of our study by estimating the effects of removal of tariffs among 14 countries and 2 regions, which, together, over the global trade. A Bilateral Trade Model (BTM) is employed to simulate the effects of tariff removal and quantify by sector how the imports and exports of each

country and regions respond to a complete removal of tariffs. We first introduce the important features of the existing BTM and then describe how it is upgraded to incorporate the trade protection factors. Finally, the simulation results for the 16 countries and regions under three different scenarios are presented and discussed.

In the Chapter 6, we make concluding remarks and suggestions for future research.

CHAPTER TWO: GLOBAL TRADE PROTECTION: THE DATA

1. Introduction

Governments of almost all countries often intervene in trade across borders through the use of tariffs, quotas, and other non-tariff barriers (NTBs). Reductions in these trade restrictions are regularly achieved through multilateral trade negotiations or preferential trade arrangements. Complete and transparent disclosure of the trade protection data is the key to assessing the current situation of global trade protection and implementing any future trade liberalization plans. The United Nations Conference on Trade and Development (UNCTAD) has been tracking and compiling the information on world-wide trade protection measures for decades. The Trade Analysis and Information System (TRAINS), recently released by the UNCTAD, is the most comprehensive collection of publicly available information on tariffs and NTBs. It contains information on tariffs, NTBs and trade flows for most OECD countries and some 80 developing countries. For each basic Harmonized System good (6-digit level) of each country, it provides the average tariff rate, an NTB indicator and the corresponding value of imports. It therefore allows for a cross-country comparison of import controls. However, in order to obtain a complete picture of the situation on trade protection, it is desirable to have the information on how a country's outbound trade flows are restricted. Forming an idea of how a country's exports are restricted by its trading partners necessarily involves combining the information of the country's bilateral trade pattern with that of its trading partners' import regime. Since TRAINS does not provide bilateral trade data, we resort to a separate data source -- the World Trade Database (WTDB) produced by the Statistics Canada. By combining TRAINS and WTDB, we constructed a Trade Protection Database which adds to the original TRAINS the capability of providing data on trade barriers faced by each country's exports.

This chapter consists of six sections. After this introduction, we discuss the issue of trade protection measurement in section two. In section three, we briefly describe TRAINS and WTDB. Section four focuses on how the combination is carried out. An overview of the situation on global trade protection is made in section 5. Section six summarizes.

2. The Measurement of Trade Protection

This section is concerned with the measurement of trade protection for the purpose of trade policy modeling. Trade protection measures consist of two broad categories: custom tariffs and NTBs.

2.1 Tariffs

Customs tariffs are usually published in book form indicating the percentage of customs duty to be charged on commodities being imported, and they are typically classified according to national tariff classifications, which, based on Harmonized Commodity Coding and Classification System (HS), may contain as many as 13 digits. Since most of the tariffs are currently specified in

ad valorem form, measurement of tariffs entails taking the average of tariff rates at the tariff line level in order to obtain *ad valorem* tariffs at a more aggregated level. If it is desired to use some kind of weighting, an ideal but unavailable set of weights in these averages would be the level of imports that would have occurred if there were no barriers.¹

Three alternative sets of weights are suggested instead of the ideal weights: home (importing) country imports, global imports and equal weights. However, each of these sets of weights is likely to depart substantially from the ideal. Weighting by home country imports understates the ideal rates if barriers are effective in reducing imports. In addition, the computed average tariff rates may be sensitive to the commodity structure of the imports distorted by protection. Weighting by total global imports can also suffer from downward bias if the commodity structure of barriers is similar in most countries. Moreover, since each country uses the same set of weights, the country-specific import structure is not taken into account. Unweighted averages seem likely to be an even worse approximation to the ideal average since barriers against commodities with negligible trade are treated the same as those against the imports of major commodities. In addition, like world import-weighted averages, unweighted averages also ignore different countries' characteristics that would cause differences in their free-trade import levels. It is also suggested that domestic output (or demand) should be used as weights instead of trade flow. However, since domestic output (or demand) data are usually not available at the tariff line level, it is still necessary to make simple averages of tariff lines to the point where the lowest level of output classification starts.

The average tariff rates generated by using different weighting methods can be utilized as indicators of home country's tariff barriers against all of its trading partners. However, tariff rates faced by different exporters may vary for a variety of reasons. Discriminatory rates could result from regional trade agreements and an importer's refusal to grant Most Favored Nation (MFN) status to a particular exporter. It is also argued that, in reality, implicit discrimination, operating through the composition of trade in country-specific tariff schedules, far outweighs in importance the explicit discriminatory tariff practices like preferential trading arrangements. So if one chooses to focus on the issue of bilateral tariffs, then, when the relevant average is taken, the bilateral trade flows should be employed as weights to account for the compositional differences in trade.

2.2 Non-tariff Trade Barriers (NTBs)

In the literature as well as practice, two different approaches have been adopted to quantify the NTBs. These alternative approaches differ considerably in their methodology and in the nature of their empirical results. The first approach attempts to quantify trade and other economic effects of NTBs, often through the estimation of their *ad valorem* equivalents. The second, often

1 See Nogues et al. (1986)

referred to as the “inventory” approach, has been used primarily to produce descriptive statistics on the kinds, pattern and frequency of use of NTBs.

For empirical modeling, an important input is the price effect or “price wedge” associated with each NTBs - often called the tariff equivalent of NTBs. This is the difference between the free world price of a product and the domestic price which is protected by NTBs. If world prices are genuinely free, they can be obtained from world commodity markets. They can then be compared directly with the domestic prices of identical products. It might also be possible to use an economic model of an industry, together with relevant supply and demand elasticities, to compute the price wedge based on observed changes in the volume of production and trade. Since no central records exist for non-tariff nominal equivalents, they must be independently estimated. As far as modeling disaggregated trade flows with a global scope is concerned, this approach is deemed impractical because it usually involves collecting data from various sources that not readily available.

The inventory approach is to record the number, form, and trade coverage of non-tariff trade policies as determined through surveys, frequency of complaints by trading partners and government reports. For empirical analysis involving NTB inventories, two indices have been designed. One measure is a frequency index (F_j) showing the percentage of tariff lines covered by some pre-selected group of non-tariff measures, where N_i is i th tariff line, D_i is a dummy variable that takes a value of unity if one or more NTBs are applied to the i th item or zero otherwise. The above summation is made over all countries exporting to importing country j .

$$F_j = \frac{\sum D_i N_i}{\sum N_i} * 100$$

Given that matched tariff-line-level import statistics are available, in which individual countries of origin for shipments are identified, a second index showing the share of total imports subject to NTBs can be computed. This trade coverage ratio (C_j) is defined as,

where $V_{i, t-n}$ represents the value of imports in tariff-line item i in year ($t-n$), and $D_{i,t}$ is a dummy variable that takes a value of unity if an NTB is applied to the item and zero otherwise. If n and m are zero, the index is based on current trade values, otherwise it is expressed in a base year's trade weights. Holding n constant and varying m will measure the effects of changes in effective protection with constant trade weights, whereas holding m constant and varying n will measure the effects of changes in effective protection caused by changes in the structure of trade.

$$C_j = \frac{\sum D_{i,t-m} \times V_{i,t-n}}{\sum V_{i,t-n}} * 100$$

n), and $D_{i,t}$ is a dummy variable that takes a value of unity if an NTB is applied to the item and zero otherwise. If n and m are zero, the index is based on current trade values, otherwise it is expressed in a base year's trade weights. Holding n constant and varying m will measure the effects of changes in effective protection with constant trade weights, whereas holding m constant and varying n will measure the effects of changes in effective protection caused by changes in the structure of trade.

Since both the frequency index and the coverage ratio are numbers falling into the range between 0 and 1, in empirical analysis, they are typically

treated as if they were average *ad valorem* tariff rates and used as explanatory variables in models explaining trade flows at an aggregate level. In the literature, almost all the empirical studies which involve NTBs in a multi-country and multi-sector context have used one of those two ratios as NTBs indicators.

A point to note, however, is that the inventory data are compiled mainly from official publications such as national customs schedules or GATT notifications. The reliance on official sources may cause underestimating the importance of some NTBs. Furthermore, the import coverage ratio and frequency ratio measure the extent to which imports are subject to NTBs and not the degree to which they are restricted. Finally, since the coverage ratio involves the value of imports, those drawbacks associated with tariffs when the import-weighted average of *ad valorem* tariff rates are being computed will also exist in the case of NTB.

3. The TRAINS and The WTDB

As noted above, the measurement of trade protection across industries and countries involves computing the average *ad valorem* tariff rates and NTB coverage ratios based on very detailed data of tariffs, NTBs and corresponding trade flows.

3.1 The Trade Analysis and Information System

The United Nations Conference on Trade and Development (UNCTAD) has been tracking and compiling the information on world wide trade protection measures for decades. The Trade Analysis and Information System (TRAINS), recently released by the UNCTAD, is acclaimed by a leading figure in this field as “the most comprehensive collection of publicly available information” on tariffs and NTBs.² It contains, inter alia, information on tariffs, NTB and trade flows for most OECD countries and some 80 developing countries. TRAINS enables users to extract information on trade protection measures, and the associated trade flows. The data are reported for the year of 1994 for most of the countries. For each basic Harmonized System item (6-digit level), it allows for a cross-country comparison of indicators on the import regime, such as the average of tariff rate and the NTBs frequency ratio; likewise, it allows the same comparison to be made of import values. Tariff schedules for most countries contain between 5,000 and 10,000 tariff lines and products.

Tables 2.1 and 2.2 illustrate the type of data available in TRAINS. Table 2.1 shows a sample of data on U.S. imports for a few apparel products. For each 6-digit HS item, TRAINS reports, for each country, the value of imports, the Most Favored Nation (MFN) tariff rate, the rate of total charge (tariffs plus customs fees) and the NTB coverage ratio. For example, for Overcoats of man-made fibers (HS code 620193), the value of U.S. imports is about \$1.1 million. The total rate of charge (tariffs plus other custom fees) on this good is 16.1 percent, and the NTB coverage ratio is 100 percent. For NTBs, in addition to the coverage ratio, TRAINS also provides detailed information on the nature

2 Laird, S.(1996)

of the NTBs at the 8-digit HS level. For example, for Overcoats of man-made fibers (HS 620193), there are five subcategories in the U.S. HS scheme. Each of the five subcategories is subject to several types of NTB measures, which explains the NTB coverage ratio of 100 percent for the 6-digit category shown in Table 2.1. These NTB measures imposed by the U.S. are shown in Table 2.2 for the five subcategories. Each is subject to several components of the Multi-Fiber Agreement. In addition, other types of barriers are present for some of these products.

Table 2.1: The U.S. Imports Regime in 1994 for Selected Apparel Products

Product	Import (\$1000's)	MFN Range(%)	MFN Average(%)	Total Charge(%)	NTB Ratio(%)
611599	4,164	8 - 20	13.2	13.2	75

Empirical trade policy models necessarily incorporate trade policies based on aggregations of these tariff lines. TRAINS, as the examples above illustrate, has a great deal of detail. However, when aggregates are extracted from TRAINS, they are only unweighted averages of tariff rates and NTB frequency ratios. Moreover, since TRAINS does not have data on the bilateral trade flows, it cannot provide information on either the bilateral trade protection or the trade barriers faced by outbound trade flows, both of which are particularly important and interesting as far as the trade relationship among a group of countries is concerned. The Trade Protection Database, described below, will overcome these limitations of TRAINS.

3.2 The World Trade Database (WTDB)

Since TRAINS does not provide bilateral trade data, we use a separate data source – the World Trade Database (WTDB) prepared by the Statistics Canada. The main source for bilateral trade data is the United Nations Statistical Office, which collects trade data from individual countries and publishes annual yearbooks of International Trade Statistics. But the UN Statistical Office does not attempt to supplement the reported data to fill in missing values or make data consistent across countries or years. Statistics Canada has compiled the UN trade data on a consistent basis with commodities defined in terms of the Standard International Trade Classification (SITC) Revision 2. The resulting data set is called the World Trade Database (WTDB) and it produces annual bilateral trade values for all countries over the period of 1980-95 at the level of 4-digit SITC detail. The value of trade is measured consistently in thousands of U.S. dollars. Valuation is performed to ensure the dollar value of exports will equal the dollar value of imports for world trade in each commodity. The trade flow data reflects reported imports.

Table 2.3 shows a sample of data extracted from the WTDB for a few U.S. imports from Singapore. For each data record, the WTDB reports the importer, exporter, product, and the time series of the corresponding bilateral trade flows. For example, in 1995 the U.S. imported from Singapore about \$ 3.1 million of the commodity under Fatty acids, acid oils, and residues (SITC 4313).

Table 2.3: The Bilateral Trade Flows between the U.S. and Singapore
(In thousands of US Dollars)

4. The Trade Protection Database

The TRAINS and the WTDB are both unique in that they collect the most comprehensive information on trade protection measures and bilateral trade flows, respectively. By combining them together, we create Trade Protection Database (TPD) which has the capability of providing information on the trade barriers faced by a country's exports as well as on the regular import barriers imposed by the country itself. From the TRAINS, we can extract three types of data for each item of 6-digit HS: (1) the *ad valorem* nominal rate for the total import charges which includes all duties and customs fees collected at national border, (2) NTBs frequency ratio, and (3) the corresponding value of imports. For simplicity, we call the rate of total import charges as "tariff rates" below.

Because the WTDB is classified by SITC, we converted the TRAINS data from its HS classification to SITC. With the help of a concordance table between 6-digit HS and 4-digit SITC, we computed the import-weighted tariff rates and NTB coverage ratios at the 4-digit SITC for each country. Bilateral tariff rates and NTB coverage ratios at higher level of aggregation than 4-digit SITC are computed by aggregating the 4-digit SITC average tariff rates and NTB coverage ratio to the desired level with the 4-digit SITC bilateral import values as weights.

As pointed above, use of the detail is important because significant differences can occur among aggregated tariff rates or NTB coverage ratios for a broadly defined commodity aggregate (Apparel, for example) that is imported from different countries. For example, within a commodity aggregate, imports from developing countries may be mostly primary or semi-processed goods, while imports from developed countries may be mostly processed goods. If tariff rates vary with the stage of processing, as they often do, then for a commodity aggregate, the average tariff faced by exports from developing countries will differ in a systematic way from that faced by developed countries. In the TPD, we capture this distinction by deriving aggregated from 4-digit SITC bilateral detail.

The final computation allows us to examine barriers from the perspective of exporters. The tariff rates and NTB coverage ratios faced by a country's exports were computed as the weighted average of all the tariff rates of its trading partners, using its exports to each country as the weights.

The resulting TPD consists of three kinds of matrices: bilateral trade flows, bilateral tariff rates, and bilateral NTBs coverage ratios, each for one category of commodity at desired level of aggregation based on 4 digit SITC. The dimension of the matrix varies according to how the trading partner countries are grouped. For a visual sample of the matrices, the appendix to this chapter presents a 63 by 63 matrices for tariff rates, coverage ratios and trade flows at the highest aggregated level. Since the matrices are too large to fit on one page, we have to break each of the three large matrices into four panels: upper left, lower left, upper right, and lower right.

5. Global Trade Protection: An Overview

Before we examine the sectoral details of a specific country, it is useful to get a general picture of the current situation in global trade protection. In this section, we present an overview based on the TPD from two perspectives: country and industry.

5.1 Global Trade Protection: A Country Perspective

The bilateral trade protection matrix is the core of the TPD, which contains very rich information for comparing trade protection regimes of different countries. In the matrix of a specific commodity, the element in row i and column j , a_{ij} , is the tariff rate or NTB coverage ratio imposed by country i on exports from country j . Therefore, the elements down a column are the import tariff rates or NTB coverage ratios imposed by a column country against its trading partners, and the elements across a row are the tariff rates or NTBs coverage ratios imposed upon the row country's exports by each of its trading partners. Taking the average of each column, we can get, for a specific category of commodity, the tariff rates or NTBs coverage ratios imposed by column countries. Similarly, taking the average of each row, we can get the average tariff rates or NTBs coverage ratios faced by each of the row countries. Therefore, we can find out which country is protected or being protected against the most by what kind of trade protection measures. Furthermore, by comparing the variation of numbers across each column or row, we can get an idea of how discriminatory certain country's import regime is or whether a country is being treated equally by its trading partners.

Table 2.4 shows the column mean and other statistical indicators for the bilateral trade protection matrix in 1994 at the highest aggregation level. For each country, we list the average tariff rate, NTBs coverage ratio, and the corresponding coefficient of variation (COV)³, which we use as an indicator of the degree of discrimination of that country's import regime. The table is sorted by the average tariff rate. A country is more protected the higher the tariff rate or NTBs coverage ratio. A country's import regime is deemed more discriminatory the larger its coefficient of variation. In table 2.5, we compute the Spearman rank correlation of per capita GNP of each country with its average tariff rate, NTBs coverage ratio and the coefficient of variation, respectively.⁴

³ Coefficient of variation is defined as the ratio of standard deviation over mean.

⁴ See Kendall, Maurice and Jean Dickinson Gibbons (1990) for detailed discussion of rank correlation; the number in the parenthesis is: Probability $> | \text{Computed Coefficient} |$ under H_0 : Real Coefficient = 0; namely, the smaller this number is, the more statistically significant is the computed correlation coefficient.

Table 2.5: Rank Correlation Between Per Capita GNP and Import Regime Indicators

No. of Observations: 61

	Rate/Ratio	Degree of Discrimination
Tariff	-0.71 (0.00)	-0.24 (0.06)
NTBs	0.27 (0.04)	0.27 (0.03)

The correlation coefficients show that, in a relative sense, the richer a country is, the lower is its average tariff rate, and the less discriminatory is its tariff structure. However, when it comes to the NTBs, the situation is exactly the opposite: the richer a country is, the higher is its average NTBs coverage ratio, and the more discriminatory is its NTBs structure. In a word, mixed results come out of the efforts to discover the relationship between the level of a country's per capita income and its import protection regime. Two explanations can be put forward. First, implementing NTBs usually involves high administrative cost and thus poor countries tend to resort to tariffs both as a means of protection and as source for revenues in government finance; second, countries, especially developed ones, use NTBs to offset the diminished tariffs negotiated in the various GATT rounds.

In table 2.6, we list the same statistics as table 2.4 except that this time they are computed for the rows. Thus we are comparing protection faced by exports out of different countries. Again, the table is sorted by the average of tariff rates, with the countries at the top suffering the most protection from the rest of world. The rank correlation coefficients between per capita GNP and trade protection indicators are as follows:

Table 2.7: Rank Correlation between Per Capita GNP and Protection Faced by Exporting Countries

No. of Observations: 61

5.2 Global Trade Protection: An Industry Perspective

For each matrix, the last column and row stores the averages of the corresponding row and column, respectively. One element in the matrix which has been left out so far on purpose is the one in the lower right corner, and it holds the weighted average of all the elements other than those in the last column and row. Since we have a trade protection matrix for every commodity, the number in the right low corner of a matrix can be interpreted as the average tariff rate or NTBs coverage ratio imposed on that specific group of commodity on the world market. In the current version of TPD, the commodities have been aggregated according to Inforum 120-trade-sector scheme.⁵ Taking the number in the lower right corner of each of the 120 matrices, we get the average tariff rates and NTBs coverage ratios imposed upon commodities from those 120 sectors, which help us to examine the global trade protection from an industry perspective. Table 2.8 and 2.10 list the twenty most- and least-protected trade sectors by tariffs and NTBs, respectively.

Four rank correlation coefficients are calculated in table 2.9 and 2.11: the first is between the tariff rates and NTBs coverage ratios, the second between their respective ratios of standard deviation, and the last two are those between industries' world trade shares and tariff rates/NTBs coverage ratios. The findings are: in a relative sense, if an industry is highly protected and discriminated against by one type of trade barriers, it tends to be highly protected and discriminated against by the other type as well. A high level of protection appears to be given to large trade sectors.

5.3 Summary

Despite many years of multilateral trade negotiation and unilateral cuts in trade protection measures, the current level of overall trade protection is still high. It also varies considerably across countries and industries. Without digging into commodity details, we examine the overall trade protection regime from two perspectives: country and industry. Here are some findings:

- Countries of lower income tend to impose higher tariffs and more discriminatory tariff structure against imports from their trading partners.
- Countries of higher income tend to impose higher NTBs and more discriminatory NTBs structure against imports from their trading partners.
- Exports coming out of higher income countries tend to be more protected but less discriminated against in the form of tariffs by the rest of the world.
- Exports coming out of lower income countries tend to be more protected and discriminated against in the form of NTBs by the rest of the world.
- If an industry is highly protected and discriminated against by one type of trade barrier, it tends to be highly protected and discriminated against by the other type as well.
- High level of protection tends to be given to large trade sectors.

⁵ In terms of the level of aggregation, Inforum 120 trade-sector scheme is roughly in concordance with 4 digit International Standard Industrial Classification (ISIC).

CHAPTER THREE:

ESTIMATING THE IMPORT-REDUCING EFFECTS OF TRADE BARRIERS

1. Introduction

In this chapter, an econometric investigation of trade protection barriers across countries and industries is presented. Specifically, we use a model that is based on the monopolistic competition trade model and 1994 cross-country data on trade barriers, trade flows, and production to estimate the import-reducing effect of trade barriers including both tariffs and NTBs. We used the most updated disaggregated cross-country, cross-industry data on manufactured goods and, unlike previous studies, our sample covers a broad range of countries -- more than 70 in all -- including countries from the most developed ones like those in the G-7 group to the least developed ones such as Bangladesh. By pooling across both industries and countries, we can conduct estimation based on a very large sample of data, an important advance over the previous studies. Moreover, since we have access to the most updated data, the results from this study contribute to a better understanding of the recent situation on the relevant issues. Other studies known to us use data now at least ten years old data. We estimate the effects of both tariffs and NTBs, with the latter being categorized into several different types according to their functional features. In the equation estimation, we specify an empirical model which is capable of capturing the stylized facts fairly well and helps generate more sensible and econometrically efficient estimates. Finally, our econometric framework is designed to control for the simultaneous determination of flows, trade barriers and production.

This chapter has six sections. The next section reviews the literature. In section III, we specify an empirical model based on the monopolistic competition model of trade. Section IV is devoted to the description of how the data set in this study is constructed. In section V, we discuss the estimation and present the results. The last section concludes.

2. Review of Literature

Three important factors contribute to a successful estimation of the effects of trade barriers: (1) theoretical foundation, (2) empirical model specification and (3) data support. In this section, I will briefly review the literature from those different perspectives.

2.1 An Overview of the literature

This study is built upon a relatively small amount of literature. The topic has long intrigued the profession, however, the substantial data requirement usually involved in this kind of study is so demanding that comprehensive studies did not appear until late 1980's, when progress in information technology made the task less onerous. In table 3.1, we briefly summarize the key features of several representative studies closest to this one.

Table 3.1: Summary of Representative Studies

Author(date)	Theoretical Model	Data Sample Coverage	Empirical Model	Major Findings
Leamer (1988a)	Generalized factor proportions model	Fourteen OECD countries; nineteen commodity categories in 1978.	Regress domestic output on capital, labor, tariffs and commodity dummies; also do the same regression for each industry separately.	Measured trade barriers have a clear effect on the composition of output; Credible estimates of trade barriers may require simultaneous treatment for the trade barriers.
Leamer (1990)	Generalized factor proportions model	Fourteen OECD countries; ten commodity categories in 1983.	Regress imports on tariffs and NTB's with importer and commodity dummies; Bayesian method is used to help to generate sensible coefficient estimates which vary across importers and commodities.	The model that accounts for differences in commodities and countries shows that NTB's effects are difficult to detect, whereas the effects of tariffs are more substantial.
Lawrence (1987)	Monopolistic Competition Model	Thirteen OECD countries for the period of 1970-1983; Twenty-one manufacturing sectors.	Regress import penetration ratio on world production share, distance and country dummy.	Japan has an unusually low volume of imports in manufactures.
Harrigan (1993)	Monopolistic Competition Model	Thirteen OECD countries; Twenty-eight manufacturing sectors in 1983.	Regress the share of bilateral imports in aggregate spending on exporting countries' output, bilateral trade barriers and transport cost.	In 1983, imports were not reduced very as much by NTBs; transport cost and tariffs had large negative effects on imports.

Table 3.1: Summary of Representative Studies (continued)

Author(date)	Theoretical Model	Data Sample Coverage	Empirical Model	Major Findings
Ray (1981b)	Generalized factor proportions model	The U.S. data in 1970 at 4-digit SIC level	Imports and trade barriers equation are simultaneously estimated; factor intensity and NTBs are included in the imports equation.	The NTBs have no apparent concurrent impact in the structure of imports across the manufacturing sectors.
Trefler (1993)	Generalized factor proportions model	The U.S. data in 1983 at BEA Input-Output classification level.	Import penetration ratio equation and NTBs equation are simultaneously estimated in a Tobit model; factor shares and NTBs are included in the import penetration ratio equation.	When NTB are modeled endogenously, their restrictive impact on imports is much larger than otherwise.
Lee and Swagel (1995)	Monopolistic Competition Model	Forty countries; twenty-eight manufacturing sector in 1988.	Import penetration ratio and NTBs are simultaneously determined; output share, distance and trade barriers are included in import equation.	The structure of NTBs across countries and industries can be explained by sectoral conditions, which is consistent with the political-economy explanations of trade protection.
Harrigan (1996)	Monopolistic Competition Model	Twenty OECD countries; Twenty-eight manufacturing sectors in 1985.	Regress bilateral imports on exporting countries' output and commodity, exporter, and importer dummies.	The openness between Japan, the US and the EU countries differs significantly.

2.2 Theoretical Foundation

When studying the effects of trade barriers on trade flows, a natural starting point is a theoretical model describing what trade patterns would be in absence of trade barriers. The usual practice in the literature is then to modify the original model by adding variables related to trade barriers. Therefore, how one models the effects of trade barriers on trade flows, to a large extent, depends on one's choice of trade determination model.

The Ricardian model is the cornerstone of international trade theory, and it attributes comparative advantage entirely to differences in labor requirements of production. Its most important implication is that there is complete specialization in equilibrium under free trade. If relative labor costs of production could be observed, a simple regression of trade on these labor costs would suffice to test the theory and then make inferences on the trade pattern. However, observing relative labor requirements has at least two almost insurmountable obstacles: first, relative labor requirements are just as difficult to observe as relative autarky prices; second, comparing labor requirements in all countries of the world poses prohibitively practical difficulties. It is no surprise that we do not find, in the literature, any study of the trade barriers effects being made within the Ricardian framework.

The Heckscher-Ohlin (H-O) model has occupied a central place in trade theory for much of the post-war period. It says that countries will tend to export those goods which use relatively intensively the relatively abundant factors of production. Put differently, countries will tend to export the services of their abundant factors, embodied as factor content in the goods they trade. The H-O model is generally regarded as superior to the Ricardian model because it offers an intellectually more sophisticated explanation of trade. Leontief's (1954) seminal application of the H-O model of factor proportions stimulated a large body of research that continues today in an effort to more rigorously test the theory. Nonetheless, it remains true that no unambiguously correct and conclusive test has been formulated and applied. Realizing that a full understanding of trade pattern seems to require some departure from the H-O assumptions, economists resort to a "generalized factor proportions model" as a theoretical basis for empirical work and adopt a new strategy which is, as characterized by Leamer and Levinsohn (1994), "estimate, don't test!". The generalized factor proportion model allows for factors beyond just capital and labor. As a general approach to understanding trade, the factor proportions theory has stood remarkably well to the empirical scrutiny of commodity composition of trade.

Within the framework of the generalized factor proportions model, Edward E. Leamer is the leading figure in exploring the empirical issues on the effect of trade barriers. In a series of studies which started as Leamer (1974) and culminated as Leamer (1990), Leamer gives this issue a more persistent and comprehensive treatment than anyone else does in the literature. Leamer's contributions range from a building theoretical foundation for empirical models

suitable for cross-section estimation, and discussing the data problems caused by the dimension of the data sets to applying particular econometric techniques to the estimation of the effects of trade barriers. Leamer (1990) estimates the effects of trade barriers based on cross-country as well as cross-commodity variability of barriers and imports. Although it has been hailed as the best attempt at the relevant issues, Leamer's model is not free from the common weakness of the factor proportion model, namely its inability to address issues of the bilateral patterns and gross volume of trade. In a strict sense, the model derived by Leamer is for the determination of net trade flows. However, when it comes to the empirical study, the trade barriers' impact on gross import is what should be under investigation. In a word, Leamer's empirical model specification is supported only by a loose theoretical justification.

Beginning in the late 1970's, an initially small group of theorists began to develop a different approach to international trade, which later became known as the New Trade Theory. This line of work was, in part, motivated by the observation that much international trade appears to be in goods that are quite similar. The core of the new trade theory is the so-called monopolistic competition trade model as summarized in Helpman and Krugman (1985). Two major assumptions distinguish the monopolistic competition trade model from various traditional factor proportions models. The first is that there are internal economies of scale at the level of the firm; the second is that there is an aggregate demand for variety in goods. This demand for variety can come from variety-loving and/or heterogeneous consumers, or from final goods production processes that make use of differentiated intermediate products (Ethier, 1988). Because of the interaction between scale economies and demand for variety, in equilibrium each firm in an industry produces a single differentiated product.⁶

One of the major implications of the model is that the volume of trade is much larger than it would be if differences in international factor endowments were the only cause of trade. The model gives predictions about the equilibrium volume of trade:⁷

$$M_j^n = s_j (y^n - y_j^n) \quad (1)$$

where M_j^n is the total gross import of good n by country j ; m_{ij}^n is the gross import

$$m_{ij}^n = s_j y_i^n \quad (2)$$

of good n by country j from country i , s_j is country j 's share of total world

⁶ Bhagwati, Panagariya and Srinivasan (1998) provide an excellent survey of various kinds of models in this literature.

⁷ The assumptions are: identical, symmetric, homothetic preferences worldwide; identical technology; sufficiently 'similar' factor endowments; and free trade.

spending; y_j^n is output of industry n in country j ; y^n is the total world production of good n . Equation (1) and (2) provide a basic framework to estimate trade pattern and gross volume of trade. This frictionless model predicts that a country's import of good n is proportional to the amount of good n produced outside that country.

Lawrence (1987) was the first to use the monopolistic competition model to specify predicted volume of trade and to use disaggregated data on production and trade flows to determine which countries and industries differ significantly from the model prediction. Lawrence's conclusion that Japan has an unusually low volume of imports has attracted considerable attention in the literature. Harrigan (1993) investigates import-reducing effects of trade barriers in OECD countries for the year of 1983. His model is based on Equation (2). Rather than attributing any deviation of actual imports from predicted imports to the effects of protection as did in Lawrence (1987), Harrigan explicitly adds measures of trade barriers to the original model so that he can directly examine the impact of trade barriers on trade flows. His finding is that in 1983 tariffs and transport costs were a more substantial barrier to trade in manufactures between developed countries than were NTBs. In a follow-up study, Harrigan (1996) addressed a similar issue using a slightly different version of his 1993 model. Lee and Swagel (1995) was another recent study of trade barriers within monopolistic competition framework. Theirs has so far been the most comprehensive study, in which they investigate the trade flows at 3-digit ISIC just as Harrigan (1993) did, but the number of countries that they covered was almost triple that of Harrigan (1993). However, their focus is more on the political economy determinants of NTBs than on the impact of protection (both tariff and non-tariff measures) on disaggregated trade flows.

2.3 Data Support and Empirical Model Specification

Strong data support is critical to reliable empirical estimation. It is more so for the estimation of the effect of trade barriers, which usually involves data from multiple sources including trade flows, trade protection measures, production, factor endowments and so on. All the investigations in the literature face the same fundamental problem, which is caused by the dimension of those data sets. In terms of time dimension, it is usually easy to obtain time series data on trade flows, but, for trade protection data, it is extremely difficult. In terms of the number of countries, for a long time, only OECD countries published reliable trade protection data. It is not until recently that a more comprehensive data set has been made available to the public, namely the Trade Analysis Information System (TRAINS). In terms of the number of commodities, the situation is much better --- we have many commodities. It is accordingly essential to pool across countries and/or commodities to estimate the effects of trade barriers.

Leamer (1990) estimated a model similar to:

$$\log(M_i^n) = a_i + b_n + (c_i + d_n)NTB_i^n + (e_i + f_n)TAR_i^n + u_i^n \quad (3)$$

where i is importer, n is commodity, M is imports, TAR is the tariff rate and NTB is NTB coverage ratio. He used one-year trade protection and import data from 14 OECD countries with commodities disaggregated into 10 categories. In order to capture trade barriers' import-reducing effects that vary by importers and commodities, he pooled across both countries and commodities and controls for their difference by dummy variables. One contribution of his paper was that he used a Bayesian estimation method to overcome the lack of degrees of freedom usually required by such kind of dummy variable model. However, Leamer did not hesitate to mention his uncomfortableness with the fact that he had to resort to cross-commodity variation to carry out the estimation, because it was like estimating a demand equation by comparing demand for different commodities.

Lawrence (1987), for the first time in the literature, used a monopolistic competition model to investigate the issue of openness. His model was a variant of Equation (1),

$$\log(M_i^n / DU_i^n) = a_n + b_n \log(y_i^n / y^n) + c_n \log(T_i^n) + u_i^n \quad (4)$$

where DU is domestic use (production + imports - exports), T is transaction cost. Instead of modeling trade barriers explicitly, he attributed deviations from model predictions to trade protection measures. Free from the dimensionality constraint imposed by the paucity of trade protection data, he was able to run regressions by industry based on a panel of 13 OECD countries for the period of 1970-83. Lawrence avoided Leamer's dilemma of pooling across commodities, but he ignored the simultaneity problem between trade and production, which is a potentially important issue since the monopolistic model suggests that imports and production are jointly determined. Also, there may be many other sources of errors in the model, not just trade barriers.

Harrigan's (1993) data set was the same as Leamer's (1990), but since he adopted a distinct theoretical framework and thus could specify an empirical model which allowed him to take advantage of another dimension of the original data set. He slightly transformed equation (2):

$$m_{ij}^n / \pi_j = y_i^n / \pi \quad (5)$$

where, j is importing country, i is exporting country, n is commodity, π is aggregate spending. Equation (5) says that bilateral imports are proportional to each partner country's output. This implication allows him to exploit the bilateral variation in the trade pattern within a certain category of commodity and, therefore, nearly increase the number of observations by a factor of its original size. (i.e. from the number of importing countries to the product of the number of importing countries and trading partners.) For each of the 28 sectors at 3-digit ISIC level, he estimated an equation as follows:

$$\log(m_{ij}^n / \pi_j) = a_n + b_n \log(y_i^n) + c_n \log(1 + TAR_{ij}^n) + d_n \log(1 + NTB_{ij}^n) + u_{ij}^n \quad (6)$$

Harrigan also addressed the simultaneity problem between imports and output. In his study, economy-wide factor endowments were used to instrument for production. He found that in 1983, gross imports were not reduced much by NTBs, and although their levels are generally low, average tariffs had large negative effect on imports.

Puzzled over the “small ” estimates of the impact of NTBs, some trade theorists look for answers from endogenous protection literature. The theory of endogenous protection predicts that, in response to increased import competition, domestic interests will intensify their lobbying activity for protection, which implies that higher levels of import penetration will lead to greater protection.⁸ Ray (1981b) was among the first to test the prediction. He estimated trade and protection equations simultaneously for both United States and an aggregate of seven other industrialized countries, and he found no empirical evidence supporting the notion that trade protection and imports are concurrently determined. In a more recent attempt at this issue, Trefler (1993) found that, just on the contrary, taking into account the simultaneous determination of imports and trade protection results in a significantly larger estimate of the effect of protection on imports. Since both studies were based on U.S. data, the mixed results call for testing in a broader context.

With their focus on the trade protection determination, Lee and Swagel (1994) also estimated trade and protection equations simultaneously. They included in their sample both developed and developing countries, and their results turned out to be similar to Trefler's. However, due to the model specification in the paper, their work seemed to bring more debates than closure to this issue. When specifying the determinants of trade protection, previous researchers chose import competition and variables such as industry concentration, economies of scale, labor structure, occupation, foreign protection level etc., which are presumably close proxies of political-economy factors and, in this context, reasonably exogenous. However, when the sample is expanded to include many other countries, the same kinds of variables are extremely difficult to obtain. Lee and Swagel therefore had to use some readily available data such as real wage change, export share in gross output, labor productivity, sectoral share of value added. From the point of view of estimating the trade barriers' effect, we think that introducing those remote proxies of political-economy factors into the protection equation opens the door to a wide variety of endogeneity problems, precisely what their use was supposed to overcome.

⁸ Brock and Magee (1978); Hillman (1982); Baldwin (1985); and Magee, Brock and Young (1989).

3. The Empirical Model

The monopolistic competition model suggests that correlating the difference between actual trade flows and the flows predicted by the model with information on trade barriers can give an indication of the trade-reducing effects of trade barriers. One prediction from Equation (1) is that the import share of a good in a particular country is inversely related to that country's share of world output of that good,

$$M_i^n / DU_i^n = F(y_i^n / y^n), \quad F' < 0 \quad (7)$$

Three assumptions are, however, crucial for this result: similarity in tastes, absence of trade barriers, and zero transaction costs. If countries have a preference for goods made at home, shares of home goods in domestic consumption will exceed those of home goods in world production. Import barriers such as tariffs and NTBs will raise the share of home goods in home consumption relative to their share in world production. If there are international transaction costs, home goods will be relatively cheaper in the domestic market and their share in domestic consumption could deviate from that in world production. Unlike the simple linear relationship as suggested by Equation (1), it has long been observed that, as far as international trade is concerned, an economically small country is relatively more open than a large one.

In specifying the equation to be estimated, we try to add to the theoretical model those real world complexities that have been originally assumed away. We follow Lawrence (1987), Harrigan (1993), and Lee and Swagel (1994) among many others in the literature and adopt a log-linear functional form:

$$\log\left(\frac{m_i^n}{du_i^n}\right) = a_n + b * \log\left(\frac{y_i^n}{y^n}\right) + c * \log\left(\frac{du_i^n / du^n}{gdp^i / gdp^w}\right) + d * \log(Distance^i) + e * \log(1 + TAR_i^n) + f * \log(1 + NTB_i^n) + u_i^n \quad (8)$$

where,

- m_i^n = the total value of imports of commodity n by country i.
- du_i^n = the domestic demand (production+imports–exports) of commodity n by country i.
- du^n = the world total domestic demand of commodity n.
- y_i^n = the output of commodity n in country i.
- y^n = the world total output of commodity n
- gdp^i = the GDP of country i.
- gdp^w = the world total GDP.
- $distance^i$ = the trade-weighted average of the distance between country i and all its trading partners.
- TAR_i^n = the *ad valorem* tariff rate imposed on commodity n by country i.

NTB_i^n = the NTB coverage ratio imposed on commodity n by country i .⁹

a, b, c, d, e and f are parameters to be estimated.

The larger the share of a country's output in the world is, the larger portion of its domestic demand is going to be met by its own production, and thus the smaller the import penetration ratio (m_i^n/du_i^n). Distance is used as an indicator of international transaction costs. Higher transaction costs prevent a country from importing more. On top of that, the presence of tariffs and NTBs will further reduce the volume of imports. Unlike others, we also include the relative demand term which is measured as the ratio of a country's share of world domestic demand over its share of world GDP. If a country has a strong preference for a particular kind of goods, then its demand for it should be high relative to its GDP. Subsequently, the relative demand will be inversely related to the import penetration ratio if countries tend to have a preference for goods made domestically. For example, the French like drinking wine, which can be reflected on the disproportionately high consumption of wine relative to France's GDP to the world. If the French have a strong preference for wine made in France as they actually do, then the higher their demand for wine is, the relatively less amount of the demand will be satisfied by importing from abroad.

Since the production of each good is determined simultaneously with trade flow, we follow Harrigan (1992) and use factor endowments as instrumental variables for the sectoral production share. Specifically, we regress production share on factor endowments such as skilled labor, unskilled labor, capital stock and land. We then use the fitted values of production share in estimating equation (8). However, it should be pointed out that there is tradeoff associated with introducing instrumental variables. On the one hand, instrumental variables may help to get asymptotically consistent estimates; on the other hand, they can compromise the efficiency of the estimates.

As for another simultaneity problem caused by the political economy factors leading to import barriers often being erected in response to large volumes of imports, we are also going to control for it by a set of instrumental variables. Since tariff rates in most of the countries are under WTO strictures, they can be more comfortably taken as exogenous than NTBs. Moreover, because our main concern is to control for the simultaneity problem rather than to specify a structural model of trade protection, in the instrumental variables set we include all the predetermined variables as well as variables such as tariffs and NTBs faced by a country's exports, which can be justifiably treated as exogenous. The econometric strategy amounts to a two-stage estimation.

4. Data

The data requirement for this study is very large. It involves four data sets, covering all countries and industries: trade flows, trade protection

⁹ As to be detailed in later section, we calculate and include in the equation the coverage ratios of several different categories of NTBs.

measures, production and factor endowments. Ideally, in order to be consistent with the theoretical model, we should include in our sample as many countries and commodities as possible. However, at a more disaggregated commodity level, we end up with fewer countries and hence smaller number of observations for each commodity category.¹⁰ In another word, there is a trade-off between the sample size in terms of country and commodity. After balancing between the advantages and disadvantages, we settled on a disaggregation level of 28 industries, i.e. 3-digit ISIC (Revision 2) so that our sample covers as many as 74 countries.

4.1 Trade Flows

The source of our trade flow data is the World Trade Database (WTDB) released by Statistics Canada. The current version of WTDB covers trade flows data for some 160 countries for the period of 1980-96. We get the unilateral and bilateral imports data in this study by aggregating the data from 4-digit SITC to 3-digit ISIC level according to a classification conversion table.

4.2 Trade Protection

The original source of trade protection data including both tariffs and NTBs is TRAINS. The trade flow weighted tariff rates and NTB coverage ratio are derived from combining TRAINS and WTDB. The tariff data in our database are the *ad valorem* tariff rate plus additional custom charges. The NTBs are classified into eight broad categories according to their functional nature as documented in the UNCTAD coding system of trade control measures.¹¹ Those categories are: 1) Tariff Measures, including tariff measures other than *ad valorem* tariffs such as tariff quota, seasonal charges, temporary duties and etc; 2) Para-tariff Measures, including custom surcharges, additional charges and internal taxes levied on imports; 3) Price Control Measures, including measures controlling price of imported articles for such reasons as sustaining the domestic price, stabilizing domestic price level, and countering the damage caused by the application of unfair practice of foreign trade; 4) Finance Measures, including regulations of the access to and cost of foreign exchange for imports and define the terms of payments. 5) Automatic Licensing Measures. 6) Quantity Control Measures, including quota, license, prohibition and so on; 7) Monopolistic Measures, including measures which create a monopolistic situation by giving exclusive rights to one or a limited group of economic operators; 8) Technical Regulations, including quality, safety, health and other regulations.

We include in our equation the tariff measures, price control measures, quantity control measures, monopolistic measures and technical measures. The para-tariff measures are dropped out because in computing the *ad valorem* tariff rate, we already include those additional charges. The finance measures are excluded because our data shows that they are rarely used in practice. The

¹⁰ Some countries do not report their data at a level as detailed as others.

¹¹ Please refer to the Appendix for a complete description of the UNCTAD coding system of trade control measures.

automatic licensing measures are excluded because, according to the UNCTAD coding system of trade control measures, they do not actually involve restriction.

4.3 Production

As specified in the model, the production data at industrial level for all countries involved is required to calculate the import penetration ratio and production share as well. United Nations Industrial Development Organization (UNIDO) makes available its database of industrial statistics at 3-digit ISIC level. The database covers 89 countries and regions. The data are generally related to the period of 1981-96 inclusive and arranged according to ISIC Revision 2. The information is presented by country, year and industry.

We take from the UNIDO database the production data for one single year: 1994. Since industrial output is reported in domestic currencies, we convert them to U.S. dollars based on exchange rates from the World Development Indicator (WDI) Database. Industrial production data is then used to calculate the output ratio and, together with import and export data from WTDB, the import penetration ratio.

4.4 Factor Endowment and Distance

Factor endowments include land, capital, skilled labor and unskilled. The data on cropland, pasture and other land areas can be taken directly from the WDI database. However, we have to compute the capital stock based on time series data on gross fixed investment, which can also be found in the WDI. In deriving the capital stock, we use an overall depreciation rate of 13.3%, the same rate as used by Summers and Heston (1990) in their construction of the Penn World Table. The International Labor Organization (ILO) publishes labor force data according to seven occupational categories. Following Maskus and Penubarti (1995), we define skilled labor as occupational category 0/1 and 2 and unskilled labor as total labor force minus skilled labor.

The distance data is downloaded from the web-site maintained by Jon Haveman.¹² In the original data set, he provides the distance between economic centers of any two countries for some 100 countries. Following the practice in the gravity model literature, we use a trade flow-weighted measure of distance between a country and its trading partners as proxy for the transaction cost.

5. Model Estimation and Results

As pointed out by Leamer and Bowen (1981) and Leamer (1988), the response of imports to tariffs and NTBs is likely to vary across industries, since it depends on the elasticities of supply and demand, which might differ widely across industries. In contrast, there is likely to be less variation in these elasticities within a given industry across countries. We choose to pool across both countries and industries and use industry dummy to control for the industry-specific effect.

Our estimation procedure involves two stages. The first stage includes two steps. In step one, for each industry, we regress production share on factor

¹² <http://intrepid.mgmt.purdue.edu/Trade.html>

endowments. The results are presented in Table 3.2. The estimated coefficients are comparable across the industries and indicate that capital stock is important to all the industries, whereas unskilled labor has a negative effect on output share for a majority of the industries. In step two, aiming at controlling for the endogeneity problem of NTBs, we regress the import NTBs coverage ratio on a set of instrumental variables which includes the tariff rates and NTBs coverage ratios faced by a country's exports plus other exogenous variables including the country's import tariff rates, distance and factor endowments such as the area sizes of different kinds of land, skilled and unskilled labor, and capital stock. Our argument is that, when it comes to a country's decision on NTBs, the tariffs and NTBs faced by that specific country's exports can be justifiably treated as given. The regression results are presented in Table 3.3. A point worthy of mentioning is that one needs to be very careful in selecting instruments, because the exogeneity of the instruments is just as important as their relevance.

At the second stage, we estimate the model as specified in equation (8) by using the corresponding fitted values of the output share and the NTBs coverage ratio from the first stage regression. As mentioned in section 3, there is a tradeoff between efficiency and consistency associated with introducing instrumental variables. For the sake of comparison, we report the estimation results with and without instrumental variables for either NTBs or output share.

Table 3.4 shows that the estimation results are in general well reconciled with the predictions of our model. Output share, relative demand share, distance and tariffs are correctly signed and statistically significant. The more a country produces a kind of goods domestically, the less it will import from abroad. The stronger a country's preference for a particular kind of goods, the less it will import from abroad since, other things being equal, a country tends to have preference for goods made domestically. Trade flow-weighted distance as a proxy of transaction cost does effectively impede the potential trade flows between countries. The presence of tariffs significantly reduces a country's imports. Our estimation shows that, assuming that domestic demand does not change, a one percent increase in the tariff rate will lead to a two percent decrease in a country's imports. Introducing instrumental variables for output share and NTBs, while having little impact on the estimates of the tariff effect, does make a difference on the estimate of the effect of NTBs. Using instrumental variables for NTBs gives the correct sign for the estimated effect of NTBs, and the estimation is also statistically significant, whereas using instrumental variables for output share leads to an enhanced effect of NTBs. However, concern has been raised over the including both output and domestic demand as independent variables. The estimated effects for tariffs and NTBs¹³, - the primary focus of this study - changes little.

The functional features of various NTBs are not homogenous. As a matter of fact, different categories of NTBs may play quite different roles in restricting imports. We categorize the NTBs into five types and calculate

¹³ The estimation results from alternative equation specifications are presented in the appendix.

coverage ratio for each of them. Then, in place of a single overall NTB coverage ratio, we include in the equation the coverage ratios for all the five different types

Note:

In column 1, no instrumental variables are used for output share; in column 2, instrumental variables are used for output share; in column 3, no instrumental variables are used for output share with the coefficient for tariff measures and price control measures being constrained to be -0.50; in column 4, instrumental variables for output share, with tariff measures and price control measures being constrained to be -0.50. In the parenthesis are the corresponding t-ratios.

instrumental variables for each different type of NTBs. In column 1 and 2 of Table 3.5, we present the estimation without and with instrumental variables

for output share, respectively. After breaking down NTBs by categories, the coefficients on output share, relative demand, distance and tariff are still signed correctly as well as statistically significant, and their magnitudes do not differ much from those from previous estimation. As far as NTBs are concerned, three of the five types of NTBs, including quantity control measures, monopolistic measures and technical measures, are estimated to negatively influence the import penetration ratio, and the magnitudes of their effects all fall into a range between -0.4 and -0.6. We found positive coefficients on tariff measures and price control measures whether or not we used instrumental variables for output share. To the extent that the estimated positive coefficients of NTBs can be explained by the theory of endogenous protection, the results in Table 3.4 seem to indicate that, when facing high import penetration ratios, a country is more likely to have recourse to tariff measures and price control measures than to quantity control, monopolistic measures and technical measures. It follows that the estimated coefficients for quantity control measures, monopolistic measures and technical measures may be, to some extent, less affected by the endogeneity problem. Therefore, we re-estimated the equation, constraining the coefficients of both tariff measures and price control measures to be -0.5, the magnitude with which we feel more comfortable. As shown in column 3 and 4 of Table 3.4, the constrained estimation results in lower R^2 , the other coefficients, however, are robust to the constraints. According to the estimation, assuming that domestic demand does not change, one percent of increase in the coverage ratio of one category will lead to roughly a 0.5 percent decrease in a country's imports.

6. Summary

We use a model that is based on the monopolistic competition model and 1994 cross-country and cross-industry data on trade barriers, trade flows, and production to estimate the import-reducing effect of trade barriers. We find that in general both tariffs and NTBs are effective in reducing a country's imports. The magnitude of the estimated tariff effect is broadly in line with that agreed upon in the literature. The NTBs are then categorized into five types, and we take one step further to study how those different types of NTBs may affect the imports differently. The results are mixed. Our estimation shows that among the five types of NTBs, quantity control measures, monopolistic measures and technical measures reduce a country's imports and the magnitudes of their estimated coefficients all fall into a range between -0.4 and -0.6. Not controlling for the NTBs' simultaneity problem may explain the fact that we have positive estimates on tariff measures and price control measures. Re-estimating the equation by constraining the coefficients on these two measures to be -0.5 leave the coefficients of the rest of the variables largely unchanged.

CHAPTER FOUR:

REMOVAL OF GLOBAL TARIFFS AND NON-TARIFF BARRIERS: A STATIC ANALYSIS FOR THE U.S.

1. Introduction

What would happen to U.S. imports and exports if all countries should remove their existing tariffs and NTBs on all commodities? It is impossible to know the answer with great certainty. However, the econometric study in the previous chapter provides estimations on the relationship between imports and the trade protection measures including tariffs and some forms of NTBs. As an application of the previous study, in this chapter we try to give an informed answer. This chapter covers two related aspects: (1) the facts -- presentation of data on the tariff and non-tariff barriers faced by U.S. imports and exports; and (2) the counter-factual analysis -- estimation of the changes in U.S. imports and exports assuming all countries remove their existing tariffs and NTBs on all commodities – the “Final Round”.

2. Tariff Barriers Faced by U.S. Imports and Exports

In this section, we present data from our Trade Protection Database (TPD). We compare the barriers that the U.S. imposes on imports with the barriers faced by U.S. exports as a result of the import protection measures of its trading partners.

2.1 Trade-flow Weighted Average Tariff Rates

Table 4.1 summarizes the results for tariffs with aggregates at the level of INFORUM LIFT sector scheme.¹⁴ It shows 1994 tariff rates faced by U.S. imports and exports. The tariff rates are computed by taking a weighted average of tariff rates at the 4-digit SITC level, with trade flows as the weights. In computing the average rates, we exclude Canada, Mexico, because trade with them is already covered by NAFTA and would not be affected by the final round. We also excluded those countries whose information on trade protection is not available from TRAINS.

In general, tariffs facing U.S. exports are higher than the tariffs which the U.S. levies on imports. This situation is well publicized for agricultural and related products. Our estimates show 1.6 percent tariffs on imported products

¹⁴ LIFT, standing for Long-term Interindustry Forecasting Tool, an interindustry-macroeconomic model of the US economy created and maintained by INFOURM.

from agriculture, forestry and fishery, as opposed to 15 percent tariffs facing exports of them. But large disparities also exist for other goods. For example, the U.S. imposes tariffs of 3 percent on Motor vehicles and parts, while similar

25	Ferrous metals	3.6	7.9	57	Gas utility	0.0	3.6

exports face duties of 11.2 percent. For Special industrial machinery, tariffs on imports are 1.8 percent, compared with 5.4 percent tariffs that exporters face. For household appliances, tariffs on imports are 3 percent, compared with 10.4 percent tariffs that exporters face.

In 42 of the 50 commodity categories, the tariff rates faced by exports exceed (by more than 0.5 percentage points) those imposed on imports. The rates on imports exceed rates on exports by this amount in only two categories. Import tariff rates are less than 5 percent for more than 90 percent of the commodity categories; Apparel and Shoes are the two sectors that are subject to the highest import tariff rates – 13.2 and 12.8 percent, respectively.

In contrast, as far as tariff rates faced by U.S. exports are concerned, more than 50 percent of the commodity groups are subject to tariff rates higher than 5 percent. Exceptionally high tariff rates faced by U.S. exports are found in commodities such as Agriculture, forestry and fishery, Food and Tobacco, Apparel and Motor vehicles.

2.2 Distribution of Trade Flows According to the Trade Barriers

The situation on U.S. trade protection can be assessed from another perspective, which is to show the amount of trade subject to various levels of trade protection. The trade protection levels can be grouped by brackets. This approach is free of the downward bias associated with taking the import-weighted average.

First, we define the brackets for tariff rates. The actual tariff rates are grouped into eight ranges: 1% and below, 1%-5%, 5%-10%, 10%-20%, 20%-30%, 30%-40%, 40%-50% and 50% and above. Then, when aggregating the trade protection data at 6-digit HS level up to 4-digit SITC level, we allocate the trade flows to their respective tariff rate brackets in accordance with their corresponding tariff rates. The allocation is made in proportion to the value of imports associated with the 6-digit HS codes within a single 4-digit SITC code. After the second step, we are able to get, at the 4-digit SITC level as well as any subsequent aggregates, the distribution of trade flows according to the predefined tariff bracket. For instance, we can show how an import's value is distributed according to the import tariff rates as specified in the predefined bracket. Based on the bilateral trade flow information, we then can derive how an export's value is distributed according to tariff rates imposed by its trading partners.

We show the distribution of the value of selected U.S. imports and exports at the INFORUM LIFT model sector scheme.¹⁵ As an appendix to this chapter, we plot the same charts for all the sectors. On the vertical axis are the values of exports or imports of 1994 in millions of U.S. dollar, and across the horizontal axis are the predefined tariff brackets. Not surprisingly, the charts reveal much variation beneath the seemingly moderate level of weighted average

15 The trade flows do not include Canada, Mexico and those countries whose information on trade protection is not available.

tariff rates. For instance, the exporters of Textiles (Sector 10) on average face about 8.7 percent tariff rate, however, more than 40 percent of their exports

Distribution of US Exports in 1994 according to Export Tariff Rates
(In millions of US dollars)

Distribution of US Imports according to Import Tariff Rates
(In millions of US dollars)

actually were faced a tariff rate over 20 percent. As a matter of fact, the charts show that a substantial amount of the U.S. exports are subject to tariff levels over 30 percent. For example, about \$2 billion of U.S. exports of Motor vehicles (Sector 43), equivalent to 12 of its total value of exports, were subject to tariff rates of over 30 percent. Meanwhile the U.S. imported around \$5.2 billion of Motor vehicles, and only about 2.5 percent were subject to a tariff rate of 30 percent. While it imposed less than 5 percent tariff rate on over 99 percent of its imports of Household appliance (Sector 40), the U.S. saw about 85 percent of its appliance exports subjected to a tariff rate higher than 5 percent. Other goods such as Fuel oil (Sector 18) and TV sets, radios (Sector 42) share a similar situation where U.S. exports face higher tariff protection than do the exports from the rest of the world in getting into U.S. market.

3. Non-tariff Trade Barriers Faced by U.S. Imports and Exports.

The NTBs are classified into eight broad categories according to their functional natures: (1) tariff measures (TM), (2) para-tariff measures (PTM), (3) price control measures (PC), (4) finance measures (Fin), (5) automatic licensing (Alic), (6) quantity control measures (QC), (7) monopolistic measures (Mono) and (8) technical regulations (TR).¹⁶ We calculate the coverage ratios for the eight categories of NTBs faced by U.S. imports and exports. Just as we do for the tariffs, the coverage ratios are computed by taking the weighted average of coverage ratio at 4-digit SITC level. For the same reason, we exclude Canada, Mexico and those countries whose information on the trade protection is not available from TRAINS. The results for imports and exports are summarized in Table 4.2 and 4.3, respectively.

Among the various categories of NTBs, the U.S. mainly relies on two of them: price control measures (3) and quantity control measures (6). According to the UNCTAD Coding System of Trade Control Measures, several trade protection practices fall into the price control categories such as administrative price fixing, antidumping measures and countervailing measures. Table 4.2 shows that the US imposes price control measures on imports of 29 of 50 commodity categories. Apparel (Sector 12) and Shoes (Sector 21) are under the most extensive protection under price control measures; their coverage ratios are 63.7 and 73.8 percent, respectively. However, it is somewhat surprising that Communication equipment (52.8 percent) and TV sets, radios and phonographs (33.1 percent) are also subject to unusually high protection. Although not as extensively used as price control measures, quantity control measures are used on 24 of 50 commodity groups. Textiles (90.3 percent) and Apparel (86.6 percent) are at the top in terms of coverage ratio.

Para-tariff measure (2) and automatic licensing (5) are, on the contrary, used quite selectively. In either case, only three commodities are affected. Four sub-sets are distinguished within the para-tariff measures: custom surcharges,

¹⁶ See appendix for a complete description of the trade control measures.

additional charges, internal taxes and decreed customs valuation.¹⁷ The three commodity groups with para-tariff measures are Food & Tobacco (Sector 9), Petroleum refining (Sector 17) and Fuel oil (Sector 18), whose coverage ratios are 21.5, 46.3 and 55.0 percent, respectively. The three commodities that are subject to automatic licensing are Food and Tobacco (Sector 17), Ferrous Metal (Sector 28) and Metalworking Machinery (Sector 32). However, their coverage ratios do not carry much information about the protection, since, as mentioned before, Automatic Licensing does not actually involve protection of any substance. The incidence of Tariff Measures is relatively high, and a dozen of commodity groups are subject to its influence. In particular, thirty five percent of U.S. imports of Shoe and Leather (Sector 21) are under protection by Tariff Measures (1) of some kinds. Our data shows that Finance Measures (5), Monopolistic measures (7) and Technical regulations (8) are not among the U.S. options of NTBs.

Table 4.3 shows that, in terms of the number of commodities, U.S. exports face more NTBs protections than imports. A striking difference from the case of imports is that U.S. exports tend to be regulated with technical measures (8) by its trading partners, and, as a matter of fact, 42 of 50 commodities are under its influence. Another major difference is that para-tariff measures (2), monopolistic measures (7) and automatic licensing (5) are used much more extensively as far as exports are concerned. Similarity does exist however. Just like the U.S., its trading partners also rely heavily on quantity control measures (6). 45 of 53 commodity groups are subject to quantity control measures (6). U.S. trading partners also use price control measures just as extensively. Finance measures are rarely used by either the U.S. or any other countries.

Aggregate summaries can obscure restrictions on specific products. Tariffs rates and NTB coverage ratios are also presented as Appendix to this chapter and describe in some product detail, by 4-digit SITC.

4. Removal of Tariffs and NTBs: A Counter-factual Analysis

What would happen to U.S. imports and exports if all countries should remove their existing tariffs and NTBs on all commodities? In Chapter three, we estimate the import-reducing effects of tariffs and various types of NTBs in an econometric framework. Our estimation indicates that the sensitivity of imports penetration ratio with respect to tariff rate is in the neighborhood of -2.0 . The estimation results for various NTBs are in general mixed, however, we do have grounds to place due trust on the estimates of three types of them, including quantity control measures, monopolistic measures and technical measures. According to our estimation, the sensitivities associated with those three types of NTBs are in the neighborhood of -0.5 . The estimated sensitivities can be good approximations of sensitivities of imports with respect to tariff rate and NTB coverage ratio, assuming domestic demand does not change. A one percent reduction of tariff rates will incur two percent imports increase. A one percent

¹⁷ See appendix for a complete description of the trade control measures.

reduction of NTB coverage ratio, will lead to 0.5 percent increase in imports. Based on the information on the sensitivities and our data on the current level of trade protection of tariffs and NTBs, we can calculate how much a country's imports will increase if it chooses to eliminate its existing trade protection. It should be pointed out that the estimated sensitivity in the previous chapter is an indicator of the cross-country and cross-industry average. By applying the same sensitivity parameter to different countries and industries, we only capture the average tendency of the response of an industry in a country to the trade liberalization shock. Consequently, the variations in the estimated changes of imports reflect those in the pre-liberalization levels of trade barriers.

4.1 Removal of Tariffs

We take the estimated sensitivity -2 as given and compute, at the 6-digit HS level, the percentage change in each country's imports that would occur if tariffs were eliminated by all countries. We then take the import-weighted average increase in imports at the 6-digit HS level to get the percentage increase at 4-digit SITC level. Since we assume the tariff cuts are nondiscriminatory, each country consequently increases its imports of the same commodity from different sources by the same percentage. To calculate the increase in each country's exports, we use bilateral exports as weights.

Tables 4.4 and 4.5 show the respective increase of U.S. exports and imports from the elimination of tariffs by the U.S. and its trading partners. The percentage increase is shown in column 5 of the tables. The levels, shown in billions of dollars in column 6, result from the application of the percentages to 1997 trade data. INFORUM's LIFT model and database are the source of 1997 data on trade and domestic production. Again, because we want to analyze trade not covered by existing agreements to remove barriers, we exclude trade with Canada and Mexico. Also excluded from the estimates are those countries whose tariff data are not available from TRAINS.

As shown in Table 4.4 and 4.5, U.S. total commodity exports would increase by \$34 billion, while imports would increase \$40 billion. In several industries, increased exports are approximately offset by increased imports. These sectors include Lumber, Fabricated metal products, Computing equipment, Household appliances, and Medical instruments. But this pattern is not typical for most industries. In terms of net exports, 27 out of 51 sectors enjoy gains. Such industries as Food & tobacco, Agriculture, Chemicals, Communications equipment, semiconductors and electronic components, and aerospace, where the U.S. have traditionally been competitive in the global market, are among the winners, with gains from exports exceeding increases in imports. Significant losers are Apparel and Shoes. Indeed, the aggregate decline in net exports is due mainly to their large import increase: \$11.7 billion in Apparel and \$3.6 billion in Shoes. Other net losers, where increased imports exceed the gain from exports, are Instruments (including cameras, watches, and photocopiers), Steel, and Motor vehicles and parts.

Tables 4.4 and 4.5 include several other useful measures. In addition to the increases in imports expected from tariff removal, Table 4.5 shows the level of 1997 imports valued in domestic port prices,¹⁸ import as a share of domestic demand, and the imports assumed to be subject to the tariff reduction. In several sectors, significant import penetration has occurred in spite of high tariffs. Apparel and Shoes are notable examples, with imports providing 47 percent and 74 percent, respectively, of domestic demand.

Several export indicators appear in Table 4.4. It indicates the portion of domestic non-defense output which is exported, the 1997 level of exports valued in producers' prices, and exports to countries other than Canada and Mexico which would be impacted by the change in tariffs.

Exports of capital goods (machinery and transportation equipment) account for about half of the increase in exports. Large portions of production of most of these industries are exported. Generally, export gains were greater than the increases in imports of capital goods. Motor vehicles and Instruments were, however, an exception to this pattern.

Although Agriculture, Food, and many capital goods sector benefit from the removal of tariff barriers, our estimates suggest that the aggregate economy experiences little direct benefit or loss in the trade balance. Gains in exports are approximately offset by increased imports. There are several reasons for this somewhat surprising result. Particular industries will benefit from open trade and they are vocal in presenting their case. Rhetoric on trade barriers tends to imply, somewhat inaccurately, that U.S. markets are completely open, while foreign markets erect barriers to keep U.S. goods out. But data show that the U.S. imposes tariffs on many goods. Import penetration has been significant in several industries in spite of important tariffs in some cases. Removal of U.S. tariffs will increase imports. While the increase in imports of labor-intensive goods such as Apparel is not surprising, impacts on some other industries are not so easily anticipated. For example, our estimate suggest that, with the removal of tariffs, exports from the Motor vehicle and parts industry will increase by nearly 17.4 percent, \$2.86 billion. Although imports of vehicles and parts will increase by a smaller percentage (5.6 percent), the \$ 3.6 billion increase exceeds the gain from exports.

The analysis examined the direct impacts of removing tariffs. There are, of course, other reasons to promote open trade. For example, open trade allows consumers to enjoy a wider variety of goods at lower prices than would be available in the restricted market. International competition tends to spur domestic productivity.

¹⁸ Imports in Table 5 are valued in domestic port prices, the value at which imports compete with goods produced by domestic industries. This valuation includes the cost of international freight, insurance and duties, as well as the cost of the good.

4.2 Removal of NTBs

Coverage ratios indicate the presence of barriers to trade, but do not give an indication of the degree to which trade is restricted by the barriers. In Chapter 3, we explored the sensitivities of imports with respect to five different types of NTBs. Our equation explains reasonably well the sensitivities of the import share in term of three types of NTBs, including quantity control measures, monopolistic measures, and technical measures. It suggests that imports are reduced by about 0.5 percent for each percent of imports covered by the three types of NTBs. Taking the estimated sensitivities as given and following exactly the same steps as we do for the tariffs, we estimated the impact on U.S. trade from the removal of each of the three NTBs. We calculated the percentage change of trade flows incurred by removing each of the three types of NTBs. The total effect is estimated by simply adding up the effects of the three types of NTBs. The value magnitude of the trade flows change is then estimated based on 1997 data on trade flows. Table 4.6 and 4.7 shows the estimated impact for 50 aggregate industries.

The impact on imports is concentrated in a few commodity groups (Textile, Apparel and Shoes). As far as exports are concerned, the impact of removal of NTBs is widespread but not significant except for five commodity groups: Agriculture, Coal mining, Food & tobacco, Fertilizers and Gas utility. Combining the information on the estimated impact with the data of imports level in 1997, we further estimate that, without NTBs, U.S. imports (from countries other than Canada and Mexico) would have been 2.1 percent (\$12.58 billion) higher than their 1997 levels and U.S. exports would have been 5.3 percent (\$18.46 billion) higher than their 1997 level. In particular, about 80 percent of the import increase is accounted for by three sectors: Textile, Apparel and Shoes.

5. Concluding Remarks

Taking a static approach, we estimate the impact on U.S. trade from removal of tariffs and NTBs. Several assumptions used in the study may influence our results. For example, measured tariff rates and NTB coverage ratios for aggregate commodity groups might be understated if barriers have been effective in reducing trade in those goods with protection. We have assumed constant sensitivities to estimate the change in exports or imports from removal of tariffs. Where import shares are already high (for example, imports of apparel and shoes into the U.S.), the constant sensitivities might overstate the increase in imports of such goods. Alternatively, where tariffs have prevented imports from penetrating domestic markets, the assumption might understate changes. Our estimation of the impact of NTBs seems somewhat crude, nevertheless we believe it is an worthwhile exercise on the basis of serious thought and solid data support. We note also that this study has analyzed commodities and has not addressed trade in services.

CHAPTER FIVE:

REMOVAL OF TARIFFS: SIMULATION WITH A BILATERAL TRADE MODEL

1. Introduction

In the previous chapter, we focused on one single country and its trade relationship with the rest of the world. We estimate the impact on U.S. trade under an assumed scenario, a “Final Round”, in which the existing trade barriers of all the countries in the world are removed. The estimation was made possible by our estimation of the sensitivities of imports with respect to tariffs and NTBs and the data on existing level of trade protection. We calculated the import increase of the U.S. as well as its trading partners. The increase in the U.S. exports was then calculated by summing up the increases of imports of all its trading partners. This approach guarantees the accounting consistency of the bilateral trade transactions. Namely, the level or change of a country’s volume of exports should be consistent with the level or change of its trading partners’ volume of imports. In principle, the same kind of computations can be done for all the other countries.

Two major assumptions were made in the study in the previous chapter. The first one is that the tariff cuts are nondiscriminatory, and each country consequently increased its imports of the same commodity from different sources by the same percentage. The second one is that the sensitivities of imports with respect to tariff cuts are uniform across countries and commodity groups. In this chapter, we first relax the first assumption by explicitly modeling the impact of bilateral discrimination on trade shares. Then, in a separate exercise, when estimating the response of imports to tariff cuts, we use country and commodity-specific sensitivities which were estimated in separate studies made by INFORUM and its foreign partners. We also expand the scope of our study by estimating the effects of removal of tariffs among 14 countries and two regions, which together cover the global trade.

A different approach is taken. More specifically, we use a Bilateral Trade Model (BTM) to simulate the effects of tariff removal and quantify by sector how the imports and exports of each country and region respond to a complete removal of tariffs. As to be elaborated later, the function of BTM is to allocate each country’s imports to their source countries in accordance with the commodity-share matrices. The sum of all the allocations of a particular product to one country then yields a consistent estimate of exports of that country. BTM is designed to ensure the accounting consistency of bilateral trade transactions at a disaggregation level of 120 sectors.

The remainder of this chapter is divided into four sections: in section II, we briefly describe the existing BTM; in section III, we discuss how the BTM is updated and improved so as to deal with the trade protection issues; in section

VI, we present and discuss the results from our simulation with the BTM under different scenarios; Concluding remarks are made in the last section.

2. Bilateral Trade Model: An Overview

BTM explicitly models the impact of tariffs on trade shares. The existing BTM was developed at INFORUM by Qiang Ma (1996). INFORUM, which stands for the Inter-industry Forecasting at the University of Maryland, was founded by Clopper Almon in 1967. INFORUM is a research organization dedicated to improving business forecasting and government policy analysis. At the heart of INFORUM's research is a set of inter-industry macroeconomic models for the U.S. and other foreign countries. These models are dynamic, and produce annual forecasts for a variety of industry indicators through at least 2010. The central role of the BTM is to link each national model and produce forecasts of trade flows that are consistent from country to country. The BTM allocates each country's imports to their source countries in accordance with the commodity-share matrices. The sum of all the allocations of a particular product to one country then yields a consistent forecast of exports of that country.

Nyhus (1975) built the first comprehensive trade model in advance of most of the national models it was to link. The linked international system, as envisaged in Nyhus' study, would work like a solar system, in which the trade model is treated as the Sun and the country models as the planets. The "Sun" draws imports and absolute domestic prices to itself and radiates exports and world prices back to the "planets". Market-clearing world prices and exports are determined simultaneously through an iterative solution process.

Unfortunately, this linking plan was never implemented. The principal reason was the trade model's heavy reliance on the role of prices in the determination of the country of origin for imports. The national models were relatively slow in their development of price forecasts because work on the price forecasting can be developed only after the "real" constant-price part of the model has been working for some time. Indeed, at the end of 1984, only the models of the United States, Japan and Italy had domestic prices as an integral part of the forecasts each model produced. Today, by contrast, domestic price projections are available in all of INFORUM's national models. By the time that the national models were ready, the first bilateral trade model was hopelessly out of date because its database was the 1962-1972 period. Furthermore, the individual country makeup of the INFORUM system had changed markedly with the addition of Korea and China.

The bilateral trade model is a multi-sectoral world trade model for 16 trading partners and 120 commodity categories. The 16 trading partners are Canada, USA, Mexico, Japan, Korea, China, Taiwan, Austria, Belgium, France, Germany, Italy, Spain, UK, the Rest of the OECD and the Rest of the World. The 120-commodity category is the classification scheme used by INFORUM international system, which is roughly consistent with the 3-digit ISIC revision 2. A list of the commodities is presented in Table 5.1. The scope of BTM is

global and covers all the world commodity trade. In particular, excluding the two aggregate regions, the total trade value of the 14 individual countries accounts for over 65 percent of the total world trade in 1995.

The centerpiece of the bilateral trade model is the trade-share matrix. Trade shares show, for a country importing a certain product, the proportions imported from each source country. It provides the fundamental trade linkage mechanism that directly connects the import demand of a country to the export supplies of its trading partners', as represented by the following matrix notation: where X is the export vector with n elements, each of which corresponds to the

$$X_{n \times 1} = S_{n \times n} * M_{n \times 1} \quad (5.1)$$

total exports in a given sector by one of the 16 countries or regions in the trade model, M is the import vector for the same sector, and S is the trade-shares matrix for this sector.

The trade shares are not constant; and, in fact, in Ma's study each element of the trade-shares matrix is a function of relative price, relative capital stock growth and other factors. The main task of the bilateral trade model is to forecast the S matrices. Mathematically, the typical S_{ij} element of the trade-shares matrix can be written as follows:¹⁹

where,

S_{ijt} = the share of country i in the imports of a given product into a given country j in year t (0 denotes the base year 1990);

P_{eit} = the effective price of the good in question in country i (exporter) in year t , defined as a moving average of domestic market prices for the last three years;

$$S_{ijt} = \beta_{ij0} * \left(\frac{P_{eit}}{P_{wjt}} \right)^{\beta_{ij1}} * \left(\frac{K_{eit}}{K_{wjt}} \right)^{\beta_{ij2}} * e^{\beta_{ij3} T_t}$$

P_{wjt} = the world price of the good in question as seen from country j (importer) in year t ;

K_{eit} = an index of effective capital stock in the industry in question in country i in year t , defined as a moving average of the capital stock indices for the last three years;

K_{wjt} = an index of world average capital stock in the industry in question as seen from country j in year t with the country weights being S_{ij0} ;

T_t = Nyhus trend variable, set to zero in the base year;

$\beta_{ij0}, \beta_{ij1}, \beta_{ij2}, \beta_{ij3}$ are estimated parameters.

The world price, P_{wjt} , is defined as a fixed-weighted average of effective prices in all exporting countries of the good in question in year t :

and the world average capital stock, K_{wjt} , is defined as a fixed-weighted average

$$P_{wjt} = \sum_i S_{ij0} P_{eit} \quad ; \quad \sum_i S_{ij0} = 1 \quad (5.2)$$

$$K_{ijt} = \sum_i S_{ij0} K_{eit} \quad ; \quad \sum_i S_{ij0} = 1 \quad (5.3)$$

of capital stocks in all exporting countries of the sector in question in year t:

The fixed weights in Equation 5.2 and 5.3, S_{ij0} , are the trade shares for the base year 1990. The use of the fixed weights ensures that the share equation satisfies the “homogeneity” condition as suggested by the demand theory. For example, if all effective prices, P_{eit} , are doubled, then a doubling of the world prices as seen by each importing country (or its import prices) leaves the price ratio unchanged. Ma (1996) estimated the BTM using time series regression on annual OECD and UN data of international trade by commodity and country of origin and destination for the 1974-91 period. Several empirical studies using BTM have been conducted.

3. Bilateral Trade Model: Update and Improvement

The BTM as developed by Ma did not address the issue of trade protection. It assumed that a country imposes a uniform tariff on the same kind of goods regardless of its country of origin, then the level of its tariff rate should not affect the relative competitiveness of its trading partners. As far as trade share equation is concerned, the same tariff factor enters into both the denominator and numerator of the relative price term, and thus its net effect is neutral.

However, as discussed in Chapter 2, the effective tariff rates faced by different exporters are not uniform for at least two reasons: 1) an importer refuses to grant Most Favored Nation (MFN) status to a particular exporter; 2) the member countries of regional trade agreements treat fellow member countries and nonmember countries differently. Moreover, in reality, the *de facto* discrimination, operating through the composition of trade in country-specific tariff schedules, can be as important as the explicit discriminatory practices.

In Table 5.2, we present the bilateral tariff matrix for selected commodities of the 120 commodity categories. As discussed in Chapter 2, the effective bilateral tariff rate imposed by importer A against exporter B is derived as the weighted average of country A’s tariff rates using the bilateral are faced by tariff rates of roughly the same magnitude, the treatment received by different trading partners however are marginally different. For instance, the US exports of meat (Sector 18) to Japan faces an effective tariff rate of 30 percent, whereas the effective tariff rate on exports of same goods from Korea was only 2 percent. The differential treatment on the part of effective bilateral tariff rates, combined with the preferential trade agreement, can presumably play a critical role in determining an exporter’s trade shares on the market of its importing partner. import flow of A from B as weights. The weighted averages of tariffs at the 6-

19 See Ma (1996) for detailed explanations.

digit HS are taken for each of the 120-commodity categories. We take into account the regional trade agreement factor in this calculation so that the bilateral tariff rates between two countries are set to be zero if they are members of the same regional trade agreement.

It is apparent from Table 5.2 that the effective bilateral tariff rates between an importer and its trading partners are far from uniform. Although, except in the cases when regional trade agreement is involved, trading partners

In order to make the BTM capable of dealing with trade protection issue, we add the bilateral effective tariff rate into the import-share equations. Specifically, the relative price term is modified as following,

where τ_{ij} is the effective bilateral tariff rate imposed by importer j on exporter i . It should be pointed out that, by introducing bilateral tariff rate into the trade

$$\frac{P_{eit} * (1 + \tau_{ij})}{P_{wit}} , \quad \text{and} \quad P_{wjt} = \sum_i S_{ijt} P_{eit} (1 + \tau_{ij}) ; \quad \sum_i S_{ijt} = 1 \quad (5.3)$$

share equation in this way, we assume that the bilateral tariff structure is constant over the period of estimation since we do not have the time series data of tariffs.

The existing BTM was estimated using trade data in the period of 1974-91. In updating the BTM, we use the 1980-95 data from WTDB, which is more up-to-date and consistent than the data available to Ma. The significant disaggregation by commodity categories and by import markets in the trade model entails estimation of an unusually large number of trade share equations. For each of the 120 trade sectors, there are 242 possible share equations ($=16 \times 16 - 14$), one for each off-diagonal element of the trade-shares matrix, plus the diagonal element representing the intra-regional trade for the rest of OECD and the rest of the World. For the whole trade model, therefore, there are 29,040 possible trade-share equations. After eliminating cells with less than 5 observations in the sample period (1980-95), a total of 23,088 equations were actually estimated.

In estimating the share equations, a ‘search’ procedure is used to explore the parameter space and to retain only estimates with correct signs and reasonable magnitudes. This search-estimation methodology is similar to the one used by Ma (1996) but refined by adding ‘reasonable magnitude’ as a second searching criterion. More specifically, in estimating the share equation, constraints are put on the parameters for the relative price and relative capital stock terms. The estimated parameter for the relative price should be negative and the one for relative capital stock positive. Moreover, their absolute magnitudes should not be higher than a critical value, beyond which the parameter is deemed unreasonable.

Depending on whether the constraints are binding, seventeen different equation specifications are searched and estimated, more than doubling that in Ma’s methodology. The seventeen different specifications are summarized in Table 5.3. The lower bound we choose for the parameter of relative price is

minus two and the upper bound for that of relative capital stock was four. The limits were based on experience with Ma's BTM; implausible results were connected with values outside this range.

4. Simulations: Removal of Tariffs among the 16 Countries and Regions

4.1 Simulations under Assumption of A Uniform Parameter of Sensitivity

In this section, we use the updated and improved BTM to simulate removal of tariffs among the 16 countries and regions. The simulation is carried out as a two-step procedure. In step one, we calculated how much each country's imports will increase in response to a complete removal of their current tariffs. In step two, through the BTM run, the changed levels of imports from each country and region involved are then translated into a changed level of exports of each of their trading partners. In the first step, we calculate the increase in imports based on each country's current level of tariff rate and our

Table 5.3: Different Specifications in the Trade Share Equation

No.	Variable(s) Included	Constraint(s) Imposed
1	P, K, T	None
2	P, K, T	$\beta_p = B_p$
3	P, K, T	$\beta_k = B_k$
4	P, K, T	$\beta_p = B_p$ and $\beta_k = B_k$
5	P, K	None
6	P, K	$\beta_p = B_p$
7	P, K	$\beta_k = B_k$
8	P, K	$\beta_p = B_p$ and $\beta_k = B_k$
9	P, T	None
10	P, T	$\beta_p = B_p$
11	K, T	None
12	K, T	$\beta_k = B_k$
13	P	None
14	P	$\beta_p = B_p$
15	K	None
16	K	$\beta_k = B_k$
17	T	None

Note: P: the relative price.
K: the relative Price.
T: the Nyhus time Trend.
 β_p : the estimated parameter for P.
 β_k : the estimated parameter for K.
 B_p : the lower constraint for β_p .
 B_k : the upper constraint for β_k .

120 commodity categories by each of the 16 countries and regions. As the second step and with a new level of imports as inputs, the BTM runs under the scenario that effective bilateral tariff rates are reduced to nil. The results are the assumed sensitivities of imports with respect to the tariff change. The methodology is the same as the one we use for the U.S. in the previous chapter. After the first step, we will have obtained a new level of imports of each of the estimated exports of each of the 120 commodity categories for each of the 16 countries and regions, reflecting both the change in the level of imports and the change in the trade shares due to the tariff cuts. Simulations under three different scenarios are made. The first one is the so-called baseline scenario, a situation in which we assume there is no change whatsoever in the tariff rates. The other two are the adjustment scenarios. Under the first adjustment scenario, we assume the tariff cuts affect both the level of imports and the trade shares. Under the second adjustment scenario, we assume the tariff cuts affect only the level of imports but leaves trade shares unchanged.

Comparing the results under adjustment scenarios with those under baseline scenario, we expect to: 1) find out what is the overall impact of tariff cuts on countries' trade performance; 2) disentangle the 'level' effects and 'share' effects from the overall effects, and therefore highlight the effects of the bilateral discrimination. More specifically, the 'level' effects increase a country's exports since, with trade shares given, the increased level of imports is always translated into increased level of corresponding exports, or trade creation. However, the 'share' effects do not necessarily work in the same direction of the 'level' effects. A country more discriminated against than its fellow competitors, will certainly benefit more from the trade liberalization than those who have previously been treated favorably. The purpose of our study is to quantify the fine difference between trade creation, trade diversion and the overall effects of the global trade liberalization.

Our simulations are done for the period of 1990-95. We assume the global tariffs are completely removed in 1995 for three reasons: 1) we would like to assess a situation as current as possible; 2) most of our tariff data are that of 1994; 3) 1995 is the base year of the newly updated BTM.

The baseline scenario assumes that the global trade regime remains unchanged. Figures generated under the two adjustment scenarios are presented as percentage differences from the baseline figures to highlight the changes incurred by the policy shock. The difference between these two differences can then be attributed to the 'share' effects, or the changes brought by eliminating the *bilateral* discrimination *per se*.

The simulation results are presented in Table 5.4 - 5.7. In Table 5.4, we first present the change in the aggregate imports of all the 120 sectors of each of the 16 countries and regions. The changed imports serve as inputs of the BTM. Since, under either of the adjustment scenarios, the responses of imports to the

removal of tariffs are the same, only two columns were presented – column one for the actual values of imports (in millions of US dollar) in 1995 and column two for the increase of imports in response to the tariff cuts presented as percentage difference from the base. As shown in the table, percentage changes of a country's imports are directly related to its levels of tariff rates prior to the liberalization. China and the Rest of the World are estimated to increase their imports by 28 and 26 percent, respectively. South Korea and Taiwan form the second tier of countries in terms of the magnitude of import increases, 17 and 18 percent, respectively. The import increases for the third tier of countries are from 6 to 10 percent, including the U.S., Canada, and the Rest of OECD. The EU countries, the bulk of whose trade has been conducted within the EU and already been liberalized, all see their imports increase by less than 6 percent.

In Table 5.5, simulation results are then shown for the aggregate exports of all the 120 sectors. For every country and commodity category, four columns are presented: column one for the actual values of exports in 1995, column two for the overall effect of the tariff cuts or the first adjustment scenario, column three for the level effect of the tariff cuts, or the second adjustment scenario, and column four for share effect of the tariff cuts, or the difference between column two and column three. Among the 16 countries and regions, exports from the US, Korea and China enjoy an enormous boost, all increasing by more than 15 percent. Japan's exports increase by more than 12 percent. The export increases of Taiwan, the Rest of OECD and the Rest of the World are also impressive, all above 11 percent. Not surprisingly, the magnitudes of increases for EU countries are relatively on the low side. Italy's exports increase by almost 13 percent, the largest increase among the EU countries, followed by Spain, Germany, France and Belgium, whose increase are 12, 11, 11 and 10 percent, respectively. Both UK and Austria see their exports increase by less than 9 percent.

The overall effects can then be broken down into 'level' effects and 'share' effects. Eliminating existing tariffs places all competitors on a level playground. Countries who enjoy bilateral preferential treatment before may lose their market shares to new competitors afterwards. It is no surprise that when taking the difference between the overall effects and the 'level' effects, we can see that the 'share' effects are negative for all the EU countries, who, prior to the trade liberalization, were entitled to preferential treatment from its fellow member countries. In particular, share effects worked strongly against Austria and Belgium, since over 50 percent of whose exports took place within the EU in 1995. On the other hand, South Korea, China, and Mexico, are the major beneficiaries of removing bilateral discriminations. The share effects for the U.S. and Japan, the two giants in the world trade market, are modestly positive, reflecting the fact that their exports are geographically diversified, and the effects incurred by eliminating bilateral discrimination should be mostly marginal. The same argument also applies to the insignificant share effects for the two regions, the Rest of the World and the Rest of OECD.

Presentations by commodity category and country are made in Table 5.6 and 5.7. Given a uniform sensitivity of imports with respect to tariffs, the

variations in the percentage increase of imports reflect the initial levels of tariff rates faced by a specific commodity group in a specific country. The BTM translates import increases into export increases. As a summary and highlight, in Table 5.8 and 5.9, we list top ten contributing commodity groups in each country in terms of import and export increases in absolute value. As shown in Table 5.8. Wearing apparel (Sector 36) appears on the top-ten list of imports in 12 (8 on the top) of 16 countries and regions, reflecting widespread protections imposed by industrialized countries on this particular commodity group. Basic chemicals (Sector 47) and Motor vehicles (Sector 106) also are well represented

on the lists of a majority of the countries. China, Korea and Taiwan share a common feature – Unmilled cereals (Sector 1) ranks high on their respective lists. On the exports side, the major motor vehicle producers all benefit tremendously – Motor vehicles is on the top of the top-ten list for the US, Japan, Germany, Austria, and Spain. Wearing apparel, on the other hand, contributes to the largest export increase in three countries and regions: China, Taiwan, Italy and the Rest of the World. Canada and the US are the two primary sources of export increases for Unmilled cereals. Crude petroleum (Sector 14) is a major contributor in Mexico and the Rest of the World in which all the other major oil producers are included.

Table 5.7 also presents breakdown of the overall effects into ‘level’ effects and ‘share’ effects. Based on the sectoral details, it can be shown that ‘share’ effects are very significant in determining the overall effects in a number of commodity categories. In particular, the ‘share’ effects in some cases are so (negatively) strong as to reverse the ‘level’ effects – a situation in which the net effect of trade liberalization on a country’s exports is negative or trade diversion occurs. We choose to examine several selected commodity groups whose results appear more illustrative.

Case 1: Taiwan’s exports of Other crops (Sector 3). The simulation shows that removal of tariffs will lead to an increase of exports by 6.4 percent, as a result of a combination of level effects of 16.9 percent and share effects of -10.5 percent. In 1995, Taiwan exported US\$ 205 million of Other crops, of which more than one-third was to the Rest of OECD where an average tariff rate of about 30 percent was in place. However, the effective bilateral tariff rate applied to imports from Taiwan was only 11 percent. In another word, Taiwan was *de facto* treated favorably by the Rest of OECD. Although Taiwan was able to increase its exports to most of its trading partners after the removal of tariffs, its exports to the Rest of OECD suffered on account of loss of the preferential treatment, which was the major reason behind the large negative ‘share’ effects.

Case 2: Japan’s exports of Vegetable & animal oils and fats (Sector 22). The simulation showed that removal of tariffs caused Japan’s exports to drop by 28.5 percent. This setback was mainly on account of Japan’s losing its market share in Korea, its largest exporting market, from 18.9 percent to 5.7 percent. France and the US, which were Japan’s major rivals in this market and had already taken a large chunk of the market, gained grounds further after the trade liberalization. In particular, prior to the liberalization, France’s exports faced twice as high effective tariff rate as Japan’s.

Case 3: France’s exports of Yarns and threads (Sector 32). In 1995, France exported 1.96 billion of Yarns and threads, of which 68 percent was within the EU. The EU countries imposed a common tariff rate of about 6 percent on imports from non-EU countries. Removal of tariffs placed France on an equal footing with other non-EU countries, and, as a consequence, its share in each of its fellow EU countries declined. Although the magnitudes of the decline of France’s share were moderate across its EU trading partners, they together

were so significant that the share effects almost completely offset the level effects, leaving France's total exports of Yarns and threads almost unchanged.

Case 4: China's exports of Boilers and turbines (Sector 76). China's exports of Boilers and turbine were estimated to increase by 9.8 percent, which is mainly attributable to its enhanced competitiveness resulting from eliminating the bilateral discriminations. More specifically, several China's major trading partners including Canada, Korea, and Taiwan have imposed disproportionately high tariff rates against exports from China. For instance, Korea imposed an effective bilateral tariff rate of 41 percent on exports from China and a relatively modest rate of less than 16 percent on exports from other countries. Similarly, Canada's tariff rates against exports from China have been more than double the rates against exports from other countries. Hence, China was able to capture more market shares from its competitors when being put on a level playground with them.

4.2 Simulations with Country- and Commodity Group-specific Parameters of Sensitivity

In the previous simulation, we used a uniform parameter of sensitivity which was derived based on an econometric estimation of cross-country and cross-commodity group data. The uniform parameter of sensitivity indicates a cross-country and cross-commodity group average tendency of how imports would react to change in tariffs. In order to model the reality as closely as possible, it is desirable to have country-specific as well as commodity group-specific parameters. Since the limitation of our dataset makes it impossible to estimate such specific parameters, we need to borrow the results from previous studies conducted by other authors.

Over the past many years, INFORUM, in collaboration with its foreign partners, has put tremendous efforts in building large-scale multi-sectoral macro models for many different countries. Estimation of import demand function has been an integral part of the model building activities. In each country model and for each commodity group, the price elasticities of import demand were determined by estimation of time series data. We can use the estimated price elasticities of import demand for each country as approximates for that particular country's sensitivities of imports with respect to tariffs. Our purpose in conducting this exercise is to provide an alternative way in examining the issue, which, however, may not be necessarily comparable with the study we presented in previous sections.

The sensitivity parameters we used are listed in Table 5.10.²⁰ Table 5.11

²⁰ The estimated elasticities are not available for France, Taiwan, the Rest of OECD and the Rest of the World. The elasticities for France and Taiwan were assumed to be the same as those of Germany and Korea, respectively. The elasticities of the Rest of the OECD were assumed to be an average of the OECD countries for which estimates were available. The elasticities of the Rest of the World were assumed to be average of China, Korea and Taiwan.

and 5.12 reported the simulation results for aggregate imports and exports. The magnitudes of the responses of imports and exports, which also reflect the variations of sensitivity parameters, are different from those of the previous simulation. Detailed presentations by commodity categories are shown in the appendix to this chapter. Top ten contributing sectors for imports and exports are presented in Table 5.13 and 5.14. It can be shown that the rankings in Table 5.13 and 5.14 share similar pattern with the ones on the previous simulation with uniform sensitivity parameter, and in fact, the rank correlation between those two pairs of tables are quite high.²¹

5. Concluding remarks

In this chapter, we simulated the impact on trade flows of a “Final Round”, a hypothesized situation in which all countries in the world remove their tariff barriers. Our investigation covered 16 counties and regions, which, together, cover the global trade flows. With continued emphasis on sectoral details, the simulations were made at a disaggregation level of 120-commodity category details. This study of extensive scope was made possible by employing a Bilateral Trade Model (BTM). The estimated impact reflected the combination of at least three factors: 1) countries’ level of tariff rates prior to the liberalization; 2) the effective bilateral discriminations among the countries and regions involved; and 3) the sensitivity parameters of imports with respect to tariff rates. Our simulation methodology was designed to identify the trade creation effect caused by lowering overall level of tariff barriers and the trade diversion effect caused by eliminating bilateral effective discriminations. Two different sets of sensitivity parameters are used in two alternative studies. The first study used a uniform sensitivity parameter, which was the result from a cross-section estimation and therefore reflected a cross- country and commodity category average tendency of how imports would respond to tariff changes. Consequently, the relative variations of estimated impact among countries and commodity groups reflect the level as well as structure of tariff rates. The second study used country- and commodity group- specific sensitivity parameters which are borrowed from studies made by other authors. Consequently, the relative variations of estimated impact among countries and commodity groups reflect the characteristics of both tariff rates and sensitivity parameters.

²¹ The Spearman rank correlation is above 90 percent.

CHAPTER SIX: CONCLUDING REMARKS

This study carried out a multi-country and multi-sectoral investigation of the impact of trade barriers on trade flows. It has several distinguished features that contribute to a better understanding of the situation on global trade barriers and their impact on trade flows: 1) quality and comprehensive data, 2) econometric estimation of key sensitivity parameters, 3) emphasis on sectoral details and 4) simulation with a Bilateral Trade Model.

The bilateral trade flow data from WTDB and trade barriers data from TRAINS were combined, resulting in a bilateral trade protection database, which describes in very detail the situation on global trade barriers including both tariffs and NTBs. One of the important features of bilateral trade protection database is that it reveals the effective bilateral discrimination in a country's trade protection regime. Analysis based on the bilateral trade protection database showed that despite many years' multilateral trade negotiation and unilateral cuts in trade barriers, the current level of overall trade barriers is still high. Trade barriers also vary considerably across countries and industries. Moreover, we also showed that the bilateral effective discrimination of trade barriers attributable to the commodity compositional difference of a country's trade structure was quite significant. We presented our analysis on the global trade protection regime from two perspectives: country and industry. Our findings are:

- Countries of lower income tend to impose higher tariffs and more discriminatory tariff structure against imports from their trading partners.
- Countries of higher income tend to impose higher NTBs and more discriminatory NTBs structure against imports from their trading partners.
- Exports coming out of higher income countries tend to be more protected but less discriminated against in the form of tariffs by the rest of the world.
- Exports coming out of lower income countries tend to be more protected and discriminated against in the form of NTBs by the rest of the world.
- If an industry is highly protected and discriminated against by one type of trade barrier, it tends to be highly protected and discriminated against by the other type as well.
- High level of protection tends to be given to large trade sectors.

An econometric estimation helped determine the marginal import-reducing impact of trade barriers. We used a model that is based on the monopolistic competition trade model and 1994 cross-country and cross-industry data on trade barriers, trade flows, and production to estimate the import-reducing effect of trade barriers. The estimation results are in general well reconciled with the predictions of the model. Output share, relative demand share, distance and tariffs are correctly signed and statistically significant. The more a country produces a kind of goods domestically, the less it will import

from abroad. The stronger a country's preference for a particular kind of goods, the less it will import from abroad since, other things being equal, a country tends to have preference for goods made domestically. Trade flow-weighted distance as a proxy of transaction cost does effectively impede the potential trade flows between countries. The presence of tariffs significantly reduces a country's imports. More specifically, our estimation showed that, assuming that domestic demand does not change, one percent of increase in tariff rate will lead to two percent of decrease in a country's imports. Whether introducing instrumental variables for output share and NTBs, while having little impact on the estimates of tariff effect, does make a difference on the estimation of NTBs. Using instrumental variables for NTBs helps to get correct sign for the estimated effect of NTBs, and the estimation is also statistically significant, whereas using instrumental variables for output share leads to an enhanced effect of NTBs. The different impact of various types of NTBs was also explored. The results are mixed however: among the five types of NTBs, quantity control measures, monopolistic measures and technical measures reduce a country's imports and the magnitudes of their estimated sensitivities all fall into a range between -0.4 and -0.6 . Not controlling for the NTBs' simultaneity problem may explain the fact that we have positive estimates on tariff measures and price control measures.

A counter-factual analysis was made for the US aimed at estimating the impact of trade barriers under a scenario – the Final Round, a hypothetical situation where all the countries in the world remove their tariff and non-tariff trade barriers. Our study showed that, as a result of the final round and with 1997 being the base year, the U.S. total commodity exports would increase by \$34 billion, while imports would increase \$40 billion. In several industries, increased exports are approximately offset by increased imports. These sectors include Lumber, Fabricated metal products, Computing equipment, Household appliances, and Medical instruments. But this pattern is not typical for most industries. In terms of net exports, 27 out of 51 sectors enjoy gains. Such industries as Food & tobacco, Agriculture, Chemicals, Communications equipment, semiconductors and electronic components, and aerospace, where the U.S. have traditionally been competitive in the global market, are among the winners, with gains from exports exceeding increases in imports. Significant losers are Apparel and Shoes. Indeed, the aggregate decline in net exports is due mainly to their large import increase: \$11.7 billion in Apparel and \$3.6 billion in Shoes. Other net losers, where increased imports exceed the gain from exports, are Instruments (including cameras, watches, and photocopiers), Steel, and Motor vehicles and parts.

The scope of our investigation was then expanded to 16 counties and regions, which, together, cover the global trade flows. The simulations were carried out at a disaggregation level of 120-commodity category details. This study of enlarged scope is made possible by employing a Bilateral Trade Model (BTM). Our simulation methodology was designed to identify the trade creation effect caused by lowering overall level of tariff barriers and the trade diversion

effect caused by eliminating bilateral effective discriminations. Two different sets of sensitivity parameters were used in two alternative studies. The first study used a uniform sensitivity parameter, which was the result from a cross-section estimation and therefore reflected a cross- country and commodity category average tendency of how imports would respond to tariff changes. The second study used country- and commodity group- specific sensitivity parameters which are borrowed from studies done by other authors.

It was shown by the simulation results that removal of existing tariff barriers could overall create tremendous new trade opportunities, and the distribution of the newly created trade among the countries and regions were largely influenced by the elimination of associated bilateral discriminations. On the imports side, China and the Rest of the World, who have the highest pre-liberalization trade barriers, are estimated to increase their imports by the largest amount in percentage. The EU countries, the bulk of whose trade has been conducted within the EU and already been liberalized, all see their imports increase by a relatively moderate amount. On the exports side, exports from the US, Korea and China enjoy an enormous boost. The export increases of Taiwan, the Rest of OECD and the Rest of the World are also impressive. However, the magnitudes of increases for EU countries are relatively on the low side.

The simulations also demonstrated that South Korea, China, and Mexico, were the major beneficiaries of eliminating bilateral discriminations, which, on the other hand, had only marginal impact on the U.S. and Japan, the two giants in the world trade market, reflecting the fact that their pre-liberalization exports are already geographically diversified. Not surprisingly, the EU countries, to a varied extent, suffered from eliminating the bilateral discrimination since they lose preferential treatment from their fellow member countries.

As far as specific commodity group is concerned, Wearing apparel (Sector 36) appeared on the top-ten list of contributing sectors to import increases in 12 of 16 countries and regions. Basic chemicals (Sector 47) and Motor vehicles (Sector 106) are also well represented on the lists of a majority of the countries. On the exports side, the major motor vehicle producers all benefited tremendously – Motor vehicles is on the top of the top-ten list for the US, Japan, Germany, Austria, and Spain. Wearing apparel, on the other hand, contributes to the largest export increase in four counties and regions: China, Taiwan, Italy and the Rest of the World. Canada and the US were the two primary sources of export increases for Unmilled cereals.

This study distinguishes itself from others in the literature by both its extensive country as well as commodity category coverage and its unique methodology in dealing with such comprehensiveness. However, a more in-depth and sophisticated study requires further research in several areas. First, the tariff data used in this study are countries' MFN rates which usually constitute the ceilings of the tariff rates being actually applied. It is desirable to compile a data set for the actual tariff rates in order to obtain more accurate estimation of the import-reducing effect of tariff rates. Second, the way in which the NTBs are quantified in this study is somewhat crude. More sophisticated approach should

be explored in this regard. Third, our study focused on the direct impact of trade barriers on trade flows and was static by nature. For a full assessment of the impact of trade liberalization, it is desirable to incorporate the linkage between trade and other parts of the economy and model the dynamic interactions. To this end, an enhanced INFORUM international model system could be very helpful.

Appendix B to Chapter two: UNCTAD Coding System of Trade Control Measures

The trade control measures are classified under broad categories according to their nature. Within the broad categories, the measures are further subdivided according to their characteristics.

1000 Tariff Measures

- 1100 Statutory Customs Duties
- 1200 MFN Duties
- 1300 GATT Ceiling Duties
- 1400 Tariff Quota Duties
 - 1410 Low duties
 - 1420 High duties
- 1500 Seasonal Duties
 - 1510 Low Duties
 - 1520 High Duties
- 1600 Temporary Reduced Duties
- 1700 Temporary Increased Duties
 - 1710 Retaliatory Duties
 - 1720 Urgency and Safeguard Duties
- 1800 Preferential Duties Under Trade Agreements
 - 1810 Customs Union
 - 1820 Free Trade Agreement
 - 1830 GSP
 - 1831 GSP to Developing Countries
 - 1832 GSP to LDCs
 - 1840 Other Specific Preferential Agreements
 - 1841 From developed to developed countries
 - 1842 From developed to developing countries
 - 1843 From developed to LDCs
 - 1844 From developing to developed countries
 - 1845 From developing to developing countries
 - 1846 From developing to LDCs
 - 1890 Preferential agreements n.e.s.
- 1900 Tariff Measures N.E.S.

2000 Para-Tariff Measures

- 2100 Customs surcharges
- 2200 Additional Charges
 - 2220 Stamp tax
 - 2230 Import license fee
 - 2240 Consumer invoice fee
 - 2250 Statistical tax
 - 2260 Tax on transport facilities
 - 2270 Charges for sensitive product categories

2290	Additional charges n.e.s.
2300	Internal taxes and charges leveled on imports
2310	General sales taxes
2320	Excise taxes
2370	Charges for sensitive product categories
2390	Internal taxes and charges levied on imports n.e.s.
2400	Decreed customs valuation
2900	Para-Tariff Measures n.e.s.
3000	Price control measures
3100	Administrative measures
3190	Administrative pricing n.e.s.
3200	Voluntary export price restraint
3300	Variable charges
3310	Variable levies
3320	Variable components
3330	Compensatory elements
3340	Flexible import fees
3390	Variable charges n.e.s.
3400	Antidumping measures
3410	Antidumping investigation
3420	Antidumping duties
3430	Price undertakings
3500	Countervailing measures
3510	Countervailing investigations
3520	Countervailing duties
3530	Price undertakings
3900	Price control measures n.e.s.
4000	Finance measures
4100	Advance payment requirement
4110	Advance import deposit
4120	Cash margin requirement
4130	Advance payment of custom duties
4170	Refundable deposits for sensitive product categories
4190	Advance payment requirement n.e.s.
4200	Multiple exchange rates
4300	Restrictive official foreign exchange allocation
4310	Prohibition of foreign exchange allocation
4320	Bank authorization
4390	Restrictive official foreign exchange allocation n.e.s.
4500	Regulations concerning terms of payment for imports
4600	Transfer delays, queuing
4900	Finance measures n.e.s.
5000	Automatic licensing measures

5100	Automatic license
5200	Import monitoring
5210	Retrospective surveillance
5220	Prior surveillance
5270	Prior surveillance for sensitive product categories
5700	Surrender requirement
5900	Automatic licensing measures n.e.s.
6000	Quantity control measures
6100	Non-automatic licensing
6110	License with no specific ex-ante criteria
6120	License for selected purchase
6130	License for specified use
6131	Linked with export trade
6132	For purpose other than exports
6140	License with local production
6141	Purchase of local goods
6142	Local content requirement
6143	Barter or counter trade
6150	License linked with non-official foreign exchange
6151	External foreign exchange
6152	Importers' own foreign exchange
6160	License combined with or replaced by special import authorization
6170	Prior authorization for sensitive product categories
6180	License for political reasons
6190	Non-automatic licensing n.e.s.
6200	Quotas
6210	Global quotas
6211	Unallocated
6212	Allocated to exporting countries
6220	Bilateral quotas
6230	Seasonal quotas
6240	Quotas linked with export performance
6250	Quotas linked with purchase of local goods
6270	Quotas for sensitive product categories
6280	Quotas for political reasons
6290	Quotas n.e.s.
6300	Prohibitions
6310	Total prohibition
6320	Suspension of issuance of license
6330	Seasonal prohibition
6340	Temporary prohibition
6350	Import diversification
6360	Prohibition on the basis of origin (embargo)

6370	Prohibition for sensitive product categories
6390	Prohibitions n.e.s.
6600	Export restraint arrangements
6610	Voluntary export restraint arrangements
6620	Orderly marketing arrangements
6630	Multifibre arrangement (MFA)
6631	Quota agreement
6632	Consultation agreement
6633	Administrative co-operation agreement
6640	Export restraint arrangement on textiles outside MFA
6641	Quota agreement
6642	Consultation agreement
6643	Administrative co-operation agreement
6690	Export restraint arrangements n.e.s.
6700	Enterprise-specific restrictions
6710	Selective approval of importers
6720	Enterprise-specific quota
6790	Enterprise-specific restrictions n.e.s.

APPENDIX TO CHAPTER THREE

Table A2.1: Alternative Estimations of Trade Protection Effects
on Trade Flows with Industry Fixed Effects

Independent Variable: Import Penetration Ratio	Equation (1)	Equation (2)
Output Share	-0.10 (-12.6)	...
GDP Share	...	0.13 (5.4)
Demand Share	...	-0.28 (-13.5)
Distance	-0.71 (-3.7)	-0.20 (-3.6)
Tariff	-1.87 (-10.7)	-2.20 (-12.3)
NTBs	-0.94 (2.3)	-1.16 (-2.0)
Adjusted R ²	0.46	0.49
No. of Observations	1675	1675

Two alternative equations were estimated:

$$\log\left(\frac{m_i^n}{du_i^n}\right) = a_n + b * \log\left(\frac{y_i^n}{y^n}\right) + d * \log(Distance^i) + e * \log(1 + TAR_i^n) + f * \log(1 + NTB_i^n) + u_i^n \quad (1)$$

$$\log\left(\frac{m_i^n}{du_i^n}\right) = a_n + b * \log\left(\frac{du_i^n}{du^n}\right) + c * \log\left(\frac{gdp^i}{gdp^w}\right) + d * \log(Distance^i) + e * \log(1 + TAR_i^n) + f * \log(1 + NTB_i^n) + u_i^n \quad (2)$$
